Norwood, Mass., U.S.A.

THE
NEW VOLUMES
OF THE
ENCYCLOPÆDIA BRITANNICA

CONSTITUTING, IN COMBINATION WITH THE EXISTING VOLUMES OF THE NINTH EDITION,

THE TENTH EDITION

OF THAT WORK, AND ALSO SUPPLYING

A NEW, DISTINCTIVE, AND INDEPENDENT LIBRARY OF REFERENCE
DEALING WITH RECENT EVENTS AND DEVELOPMENTS

VOL. I.

FORMING VOL. XXV. OF THE COMPLETE WORK

PUBLISHED BY
ADAM AND CHARLES BLACK
LONDON AND EDINBURGH
THE ENCYCLOPÆDIA BRITANNICA COMPANY
NEW YORK
MCMII

THE EDITORS

SIR DONALD MACKENZIE WALLACE,
K.C.L.E., K.C.V.O.

ARTHUR T. HADLEY, PH.D., LL.D.,
PRESIDENT OF YALE.

HUGH CHISHOLM, B.A.
(FORMERLY SCHOLAR OF C.C.C. OXFORD)

THE DEPARTMENTAL EDITORS

FOR LAW AND GOVERNMENT:

THE HON. SIR JOHN SCOTT, K.C.M.G.,
Deputy Judge Advocate General.

FOR MILITARY AFFAIRS:

SIR GEORGE SYDENHAM CLARKE, K.C.M.G.,
F.R.S.

FOR MEDICAL SCIENCE:

D. NOEL PATON, M.D., B.SC., F.R.C.P.ED.

FOR THEOLOGY:

REV. W. E. COLLINS, M.A., Prof. of Eccle-
siastical Hist. at King's Coll., Lond.

FOR MINING:

HENRY M. HOWE, A.M., Prof. of Metal-
lurgy at Columbia University.

FOR BOTANY:

D. H. SCOTT, M.A., PH.D., F.R.S., Hon.
Keeper, Todrell Laboratory, Kew.

FOR GEOGRAPHY AND STATIS- TICS:

J. SCOTT KELTIE, F.S.S., F.S.A.SCOT.,
LL.D., Sec. Roy. Geog. Soc.

FOR ASTRONOMY:

SIMON NEWCOMB, PH.D., LL.D.

FOR MATHEMATICS:

JOSEPH LARMOR, M.A., D.SC., SEC.R.S.,
University Lecturer in Mathematics,
Cambridge.

FOR ELECTRICITY:

J. A. FLEMING, M.A., D.SC., F.R.S., Prof.
of Electrical Engineering, Univ. Coll.,
London.

FOR ART:

M. H. SPIELMANN, Editor of the *Maga-
zine of Art*.

FOR ZOOLOGY:

G. H. FOWLER, PH.D.

FOR NAVAL AFFAIRS:

JAS. RICHARD THURSFIELD, M.A.

FOR BIOGRAPHY:

RICHARD GARNETT, C.B., LL.D.

FOR LITERATURE:

EDMUND GOSSE, LL.D.

FOR ECONOMICS:

WYNNARD HOOPER, M.A.

FOR RAILWAYS:

MAJOR HENRY G. PROUT, Editor of
Railroad Gazette, N.Y.

FOR MUSIC:

J. A. FULLER MAITLAND, M.A., F.S.A.

FOR GAMES AND SPORTS:

ALFRED WATSON, Editor of the *Admin-
ton Library*.

THE ASSOCIATE EDITORS

PHILIP ASHWORTH, DR. JUR.
H. M. ROSS, B.A.

FRANKLIN H. HOOPER, A.B.

PREFACE.

THE first edition of the *Encyclopædia Britannica* was prepared by "A Society of Gentlemen in Scotland," as the authors are described on the title-page, and the first weekly section was sold in December 1768 by "Colin Macfarquhar, at his printing office in Nicolson Street," Edinburgh. In 1771 the publication was completed in three volumes quarto, containing 2670 pages and 160 copper plates. From this small beginning the *Encyclopædia Britannica* has increased, in size as well as in importance, until the present edition, when completed by the new volumes, to the first of which these words of introduction are prefixed, will include more than 28,000 pages and more than 12,000 plates, maps, and other illustrations. The evolution, during the one hundred and thirty-four intervening years, was gradual. The second edition, containing 8595 pages, was completed in 1784; the third, 14,579 pages, in 1797; the fourth, 16,033 pages, in 1810; the fifth, 16,017 pages, in 1817; the supplement to the fifth edition, 4933 pages, in 1820; the sixth edition, 16,017 pages, in 1823; the seventh, 17,011 pages, in 1842; the eighth, 17,957 pages, in 1861. The first volume of the Ninth Edition was published in 1875, and the last, making a total of 21,572 pages, in 1889; and the continued public recognition of the utility of the *Encyclopædia Britannica* is strikingly shown by the fact that of this Ninth Edition more than 40,000 copies have been purchased in the United Kingdom alone during the past four years. The vitality and authority which the *Encyclopædia Britannica* has maintained through a period of almost a century and a half may be attributed to two conspicuous and distinctive characteristics, inherent in the purpose, and apparent in the execution, of its successive editions. In the first place, the publishers and the successive editors, from the beginning, brought to the undertaking an elevated view of their task. The Scottish origin of the work imparted to its inception a certain sternness of purpose, and the perfecting of the successive editions has been almost a cult, as well as a business. The second characteristic, the collaboration of distinguished contributors, was at once a corollary of the policy of the editors and a result of the reputation which the *Encyclopædia Britannica* so promptly acquired and so firmly retained. The fact has often been cited that in 1812 Dugald Stewart received for one "Philosophical Dissertation," in the supplement to the fifth edition, a sum of £1700, which was then an unprecedented remuneration for such a task, and from that time the cost of obtaining the best work seems never to have given pause to an editor. But no scale of payment, however liberal, could have enlisted the services of all the distinguished men who contributed to these nine

editions, if they had not held in high esteem the national library of reference—no longer merely a Scottish enterprise—for which they were invited to write. Sir Walter Scott, Macaulay, Arago, Hazlitt, De Quincey, Professor Playfair, Jeffrey, Charles Kingsley, Ricardo, Dr Hooker, Layard, Baron Bunson, Sir David Brewster, and Professor Owen were among the contributors to the first eight editions. The contributors to the Ninth Edition numbered more than a thousand, among them so many men of the highest distinction that their quality can only be indicated by the citation of a few such names as those of Professor Huxley, Lord Kelvin, Lord Rayleigh, Sir Archibald Geikie, Professor Max-Müller, Professor Ray Lankester, Sir William Crookes, Sir Robert Ball, Mr Alfred Russel Wallace, Mr Swinburne, and Robert Louis Stevenson. The statement that the last of the new volumes of the *Encyclopædia Britannica* will be published within a year, and that the contributors are a body no less distinguished and proportionately even more numerous, completes this brief summary of the history of the work. It has been the aim of the editors to make the new volumes so complete that no further edition will be required by the present generation, for the new portion of the work, in combination with the existing volumes of the Ninth Edition, forms, for all intents and purposes, a tenth edition.

These new volumes constitute a new, distinctive, and independent library of reference, dealing with modern developments of science, art, literature, history, biography, sociology, industry, commerce, invention, medicine and surgery, although their primary purpose is to supplement, complete, and bring up to date the Ninth Edition. The urgency of complementing that edition was even greater than the date of its publication would indicate. The first four volumes were published in 1875, the remainder appearing at varying intervals until the work was completed in 1889. Roughly speaking, the year 1880 may be regarded as a median date fairly representing the time of production of the average article. As a matter of fact, however, the Ninth Edition gave to the events of the Victorian Era a consideration less minute than that which it accorded to earlier periods of history and earlier developments of the arts and sciences. The intellectual point of view, in 1875, was influenced by scholastic traditions of which the rigour has since undergone considerable modification. It was then the practice to await patiently a future time at which what was called the historical perspective might be attained. It was thought imprudent for the writer to venture upon ice as yet but newly formed. The article upon the History of England, for example, appeared in the eighth volume, published in 1878, and of its 104 pages, 102 are concerned with events prior to the death of George IV., and only two with English history subsequent to 1830. In adopting this policy, the editors of the Ninth Edition acted in accordance with the best opinion of their generation. Since their day opinion has altered; it now seems proper that a work of reference should, as closely as is consistent with the avoidance of hasty judgment, present a full account of the most recent events and the latest phases of progress. The new volumes thus cover a period of time and a field of subject-matter proportionately larger than the period and field which the Ninth Edition added to the scope of the eighth. In selecting the point of departure for each article, as well as in deciding upon the moment at which its subject should be relinquished, the editors have been impelled by the changed conditions of our time to give more space than would have been required if they had been content to regard their task as limited by a period of twenty years, and by the degree of reticence with regard to recent events which was formerly thought to be advisable. Of the sixteen thousand articles in the Ninth

Edition, a great number needed no revision, but many others—even among the articles dealing with completed achievements, such as the lives of men long since deceased, and the histories of extinct nations—called for modification as a result of recent research. Yet, if the last twenty years alone were to be displayed to the reader, they would be recognized as marked by a progress absolutely unmatched in any equal period of the world's history.

Sir Archibald Geikie, on the occasion of the banquet held at Christ's College, Cambridge, in 1888, to celebrate the issue of the twenty-fourth volume of the Ninth Edition, expressed a wish that it were possible explicitly to contrast the conditions and prospects of the world at that time with what they had been when the eighth edition was completed in 1861, "to sketch the vast realms of knowledge and of thought that had been conquered, and to enumerate even a few of the great treasures, undreamt of in variety and value, which have been added to the sum of human knowledge." Such an apposition, displaying side by side the state of human knowledge in 1880 and its present state, would yield an even more striking lesson. Within these twenty years—and as we have seen, the period covered by the new volumes is in fact much longer—there have been astounding changes in all departments: political, social, economic, religious, scientific, literary, and artistic. Political frontiers have been altered by wars and conventions; the British Empire has vastly increased in vitality as well as in extent; America, recovered from the shock of her Civil War, has become a world-power as well as an industrial factor of the first importance; Germany, since the Franco-Prussian War, has become another industrial competitor; France has made extraordinary efforts to regain lost ground; and in the Far East, Japan has attained an unforeseen importance. The chief postulates of all branches of inquiry have been revolutionized by the widespread application of the theory of evolution and of new methods of research, while the application of science to the arts has enlarged our vision and led to new inventions in every sphere of life. Preventive medicine and aseptic surgery have come into existence and been matured; literary and artistic production has increased with almost unexampled rapidity, and much of this increase has been wholesome and deserves attention; great men and women have passed away, leaving their lives to the enlightenment of posterity, and new personalities of commanding importance have come to the front.

Containing, as they do, not only an account of this fertile period, but dealing also with many events and developments earlier in the Victorian Era, the new volumes cannot but be of use as a distinct encyclopædia of modern progress, adapted to the wants of readers who desire to confine their reading to modern topics. In order, on the other hand, to estimate the practical utility of the new volumes, if they be regarded as a supplement to the *Encyclopædia Britannica*, attention must be given not only to the inevitable gaps with which the lapse of time has pitted the Ninth Edition, but also to the position which that edition occupies in public esteem. In the United Kingdom alone more than fifty thousand persons possess the Ninth Edition and regard it as the most authoritative work of reference. In the United States more than four hundred thousand copies have been purchased. There are, therefore, in all parts of the English-speaking world, a vast body of men who habitually use the work and who await the appearance of a complement to its contents. They form the half million readers whose requirements the editors have had primarily to consider. The endeavour to meet these requirements has been made at a particularly happy moment, for, in nearly all civilized countries, a census was completed just in time to enable the

editors and contributors to avail themselves of the latest official statistics. It is not simply in respect of its statistical information that a census yields important material. It affords a large body of fresh facts with regard to public health, commerce, agriculture, and manufacture, the spread of education, and the comparative vitality of various nations, so that articles of many different sorts are far richer and fuller than they could otherwise have been. There is, indeed, no publication other than these new volumes in which the results of this world-wide census are similarly comprised.

To the twenty-four volumes of text in the Ninth Edition of the *Encyclopædia Britannica* there will now be added eleven further volumes containing 10,000 articles by 1000 contributors, 2500 new maps, plates, portraits, and other illustrations; in all about 7000 new pages, the volumes being of the same size as those of the Ninth Edition. The preparation of the new volumes was begun early in 1899, but the first year's work was largely devoted to fixing the scope and plan of the work, determining the subjects to be treated, selecting the departmental editors, to the selection by them of the contributors (a choice which could judiciously be made only by men of special technical knowledge), and to the discussions which necessarily preceded the actual task of writing. In order that the various contributions, especially those in which statistics play an important part, or in which new inventions or discoveries are described, should be checked and corrected in the light of the most recent research, all the articles have been carried in type, subject to revision by editors and contributors, and will thus be found to contain information available only a few weeks before they issue from the press. So great is the number of subjects treated in the new volumes, and so thorough their treatment, that only the most zealous goodwill on the part of the contributors has made it possible to keep the new matter within eleven volumes. This limitation was the more difficult, or from another point of view the size of the supplement was the more inevitable, for another reason. In the earlier history of the *Encyclopædia Britannica*, we find that biographies of any sort were barely tolerated. In 1776 the third Duke of Buccleuch, who was greatly interested in the project of the second edition, had much difficulty in persuading the editors to include biographical articles, which they deemed "inconsistent with the purpose of a dictionary of arts and sciences." In the case of the new volumes it has been thought necessary, in order to bring the biographical section up to date and to make it as comprehensive as other sections, to include lives of certain living men and women. The policy of the editors in this particular was to select for the most part the lives of those whose positions had become so fixed that, whatever promise of future achievement their continued vigour might give, there was no reason to believe that the general character and purpose of their work would materially change. Among the younger generation, biographies are included of reigning sovereigns or heads of states, and of some few others whose names are already of commanding interest.

A noteworthy feature of the new volumes will be the new and comprehensive index to the completed work, covering under one alphabetization the Ninth Edition and the new volumes. It will contain more than 600,000 entries, and will not only be exceedingly minute in its analysis, displaying the latest development of the time-saving art of precise indexing, but will also be by far the most complete index to the general sum of human knowledge which has ever been compiled. An index thus constructed on modern lines will greatly facilitate the use of such a work as this, for its possessor will enjoy the advantages, without suffering the disadvantages, which mark a

work of reference consisting of general treatises rather than of brief and fragmentary articles treating, after the manner of a dictionary, each subdivision of a subject under a separate heading. This dictionary system of treatment gives a far less readable result, and its practical convenience is no greater than that which the new volumes will offer with the aid of their elaborate index.

Other considerations which affected the size of the supplement were the need for new maps, called for by recent political changes and geographical discoveries, and also the necessity for copious illustration. The Ninth Edition was more amply illustrated than any former work of reference had been, and since its time the utility of informative illustration, as distinguished from mere pictures, has become more and more generally recognized. A picture of a machine, occupying a few square inches of space, conveys a clearer impression than a whole page of description. The new volumes are therefore even more copiously illustrated than were those of the Ninth Edition, and the 2500 separate drawings which were made will, it is believed, fully justify the great care which has been expended upon them. The portraits and reproductions of pictures which accompany the biographies of living celebrities, have in important instances been chosen for this purpose by the persons themselves, and the engravings have all been executed specially for the work. Every effort has been made to conserve in the new matter the high standard of the Ninth Edition, although the articles are conceived in a spirit more modern than that which obtained a generation ago. The present demand for practical details, for the industrial as well as the theoretical point of view in treating scientific developments—a natural result of the fact that new classes of readers have been stimulated to practical research by the spread of education—is another factor which contributed to the number and variety of the articles. Men who are engaged, if not literally in the manual processes of manufacture, at any rate in the immediate supervision of these processes, form a section of the reading public peculiarly exacting in their requirements. The great keenness of competition between English and foreign manufacturers furthermore makes it essential that financial, commercial, industrial, and scientific topics should not be approached from an insular and restricted point of view.

With this and many other considerations in mind, the selection of the contributors to the new volumes was a task of great delicacy. The first step was to choose the departmental editors by whom the individual contributors should in turn be nominated, and in both respects the editors believe the selections have been remarkably successful. A list of departmental editors and of contributors will be found in another part of the work, and it will be perceived that German, French, Dutch, Italian, Spanish, Russian, and Scandinavian writers have done much to round off the comprehensiveness of these new volumes, and to bring to a wider field of examination the same spirit of accurate scrutiny which characterized the Ninth Edition. It may be doubted whether in any previous work of reference the advantages to be gained from the cosmopolitan character of the staff of contributors have been so fully attained. Absolutely no discrimination was made between British and foreign writers, contributions having been invited from the men believed to be best qualified to write upon each of the subjects to be treated, and in respect especially of American writers the result has greatly added to the comprehensiveness of the work. Certain fields of applied science and industrial development have of late years owed so much to American initiative, and the subjects in regard to which it was desirable to enlist the co-operation of American writers consequently proved to be so numerous, that an editorial branch office was opened in New

York. The names of the American departmental editors and contributors speak for themselves, and for the purpose of this preface it is sufficient to say that, while *Le Figaro* described the Ninth Edition as “*Un monument littéraire auquel l'Europe savante tout entière a collaboré,*” these supplementary volumes are the product of the New World as well as of the Old.

It has already been observed that readers in the United States form a considerable proportion of the public to which these volumes may be expected to appeal, but it should be noted that the care with which American and Colonial subjects are treated would have been as sedulous if the supplement had been intended for readers in the United Kingdom only. The world beyond our own islands, and especially the English-speaking part of it, has become more intimately associated with our life and thought than it was twenty years ago. Cargoes of wool from Australia, and of cotton from America, are no longer the only enrichment we receive from the descendants of the British who betook themselves to fresh fields of enterprise. They send us new ideas and new inventions, and the fruit of their activities becomes indistinguishable from other portions of the common heritage of the race.

In allotting subjects to the various British and foreign writers whose co-operation was invited, the editors were guided solely by the desire to procure the best possible treatises, without regard merely to the measure of reputation enjoyed by individuals, and yet by this process they have associated with the work a body of men whose names will readily be recognized by the general reader. If the collaboration of eminent men can ensure success, an examination of the List of Contributors to these volumes will show that the editors have been greatly favoured. The natural impulse, when contributors are to be chosen, is to enlist the assistance of ready writers and trust to their versatility. But an authoritative work of reference cannot be created by so hazardous a method. Not only men accustomed to literary activity, but those to whom verbal expression is a mere incident of other activities—sailors and soldiers, men busied in commerce and finance, leaders in all the different divisions of life—must bring each his special knowledge to his special subject. That was the policy adopted by the editors of the Ninth Edition, and their example has been followed in the present undertaking.

The editors desire in this connexion to express their great obligation to the departmental editors, whose expert knowledge has been of incalculable service in suggesting the names of the writers best qualified to treat special subjects, and in advising the editors with respect to technical articles. A list of these departmental editors will be found at the beginning of this volume. The editors are also indebted to other eminent authorities for advice with regard to larger aspects of the task. They have not hesitated, in the course of an undertaking so important from every point of view, to ask personal counsel from those whose rank or official position precluded a direct association with the work, and in every instance their requests have met with the fullest acquiescence. More detailed acknowledgments of the editors' many obligations will be found in a note forming part of a later volume.

The practice of identifying the more important articles with their authors by means of initials has been followed in these new volumes to an even greater extent than in the Ninth Edition, although it has not seemed desirable for living writers to sign the biographies of living persons. In a few cases important articles are deliberately left unsigned, for anonymity was necessitated by the fact that only on that condition could the editors induce certain highly-placed writers to

undertake subjects which they had made peculiarly their own and yet could not treat with the detachment which is essential to objective discussion if their personalities were formally associated with what they said. In enlisting the writers of both the signed and the unsigned articles, the editors had to overcome many reluctances, due often to the difficulty in which a new writer is placed when invited to complete another man's work. The editors fully recognize that in this respect, as in others, their labours in the matter of securing the best writers have been lightened by the honour in which the *Encyclopædia Britannica* is held. Unchallenged throughout the changes of more than a century, that work stands as the classical embodiment of the highest scholarship and research. Contributors, as well as editors, are proud to associate their efforts with the traditions of an enterprise which confers some ray of its lustre upon the least among its servants.

LONDON, *May* 1902.

THE EDITORS.

ENCYCLOPÆDIA BRITANNICA.

VOLUME XXV. (AACHEN—AUSTRALIA).

PRINCIPAL CONTENTS.

- ABDURRAHMAN KHAN. Sir ALFRED LYALL, K.C.B., G.C.I.E.
- ABYSSINIA. *History*, Count GLEICHEN; *Geography*, Professor A. H. KEANE, F.R.G.S.
- ABYSSINIAN CHURCH. A. J. BUTLER, M.A., Fellow of Brasenose College, Oxford.
- ACADEMY, ROYAL. F. A. EATON, Secretary of the Royal Academy.
- ACADEMY, FRENCH. EDMUND GOSSE, LL.D.
- ACCOUNTANTS. J. G. GRIFFITHS, Ex-president of the Institute of Chartered Accountants.
- ACCUMULATORS. W. HIBBERT, F.I.C., F.C.S., Assoc. M. Inst. E.E.
- ACETYLENE. VIVIAN B. LEWES, F.C.S., Professor of Chemistry, Royal Naval College, Greenwich.
- ACHROMATIC OBJECTIVES. CHARLES S. HASTINGS, Ph.D., Professor of Physics, Sheffield Scientific School, Yale University.
- ACID AND ALKALI MANUFACTURE. Professor G. LUNGE, Zürich. Author of "Sulphuric Acid and Alkali."
- ACOUSTICS. Professor J. H. POYNTING, D.Sc., F.R.S., Birmingham University.
- ACTS OF THE APOSTLES. Rev. J. VERNON BARTLET, Mansfield College, Oxford.
- ADAMS, CHARLES FRANCIS. JAMES FORD RHODES, LL.D. Author of "History of the United States, from the Compromise of 1850."
- ADAMS, J. COUCH. DONALD MACALISTER, M.A., M.D., Fellow of St John's College, Cambridge.
- ADMIRALTY ADMINISTRATION. *British Empire*, Admiral Sir VESEY HAMILTON and JOHN LEYLAND; *United States*, Rear-Admiral W. T. SAMPSON, U.S.N.
- ADMIRALTY JURISDICTION. The Hon. Sir WALTER PHILLIMORE, Bt., Judge of the High Court of Justice.
- ADULTERATION. OTTO HEHNER, Past President of the Society of Public Analysts.
- ADVERTISEMENTS. H. R. HAXTON.
- AERONAUTICS. OCTAVE CHANUTE, C.E., Hon. Mem. Inst. C.E. Author of "Progress in Flying Machines."
- ÆTHER. J. LARMOR, D.Sc., Sec. R.S., Fellow of St John's College, Cambridge. Author of "Æther and Matter."
- AFFREIGHTMENT. The Hon. Sir JOSEPH WALTON, Judge of the High Court of Justice.
- AFGHANISTAN. *Geography and Statistics*, Sir T. H. HOLDICH, K.C.I.E.; *History*, Sir ALFRED LYALL, K.C.B., G.C.I.E.
- AFRICA. *Geography*, E. HEAWOOD; *History*, J. SCOTT KELTIE, LL.D.; *Ethnology*, Professor A. H. KEANE.
- AGRICULTURE. *United Kingdom*, W. FREAM; *United States*, CHARLES W. DABNEY, Ph.D., President, University of Tennessee.
- AGRICULTURAL MACHINERY. FRANK C. SKINNER, U.S. Patent Office, Washington.
- AINU. Captain F. BRINKLEY, Tokyo, Japan.
- AIR-GUN. Sir GEORGE SYDENHAM CLARKE, K.C.M.G., F.R.S., Governor of Victoria.
- AIRY. A. A. RAMBAUT, F.R.S., Radcliffe Observer, Oxford.
- ALABAMA. Hon. HANNIS TAYLOR, LL.D., formerly U.S. Minister to Spain. Author of "The Origin and Growth of the English Constitution."

ENCYCLOPÆDIA BRITANNICA.

(SUPPLEMENT.)

AACHEN—AARHUS

Aachen, the German name for *Aix-la-Chapelle* (q.v.).

Aalborg, capital of county Aalborg, Denmark, on the S. side of Liimfjord, 87 miles by rail N. from Aarhus, a growing industrial and commercial centre. In 1899, 1532 vessels of 250,745 tons entered the port, and 1599 of 245,681 tons cleared. The iron bridge connecting Aalborg with Nørre Sundby (pop. 3000) on the N. side of the fjord, 1250 ft. long, is one of the finest pieces of engineering in the kingdom. Population, 14,152 (1880); 19,503 (1890); 31,462 (1901).

Aalesund, a seaport town of Norway, situated on a ring of islands surrounding the harbour, co. Romsdal, on the W. coast, 145 miles N. by E. from Bergen. Founded in 1824, it is the principal shipping-place of Søndmøre, and one of the chief stations of the herring fishery. A little to the south of the town are the ruins of the reputed castle of Gangu Hrolf, the founder, in the 9th century, of the dynasty of the dukes of Normandy. Population, 5603 (1875); 8406 (1891); 11,672 (1901).

Aarau, the capital of the canton of Aargau in Switzerland, on the Aar, about 50 miles by rail from Berne, and 31 miles from Zürich. In the parliament house there is some good painted glass of the 16th century from the neighbouring Benedictine abbey of Muri, suppressed in 1841. Aarau was the residence of Heinrich Zschokke (born 1771, died 1848), the well-known Swiss novelist and historian, to whose memory a bronze statue has been recently erected in the town. Population, 6809 (1888); 7824 (1900).

Aargau, a Swiss canton, bounded on the N. by the Rhine, on the E. by Zürich and Zug, on the S. by Lucerne, and on the W. by Basel, Solothurn, and Berne. Its total area is 542 square miles. Of this 517.9 square miles are classed as "productive," forests covering 169 square miles, and vineyards 8.2 square miles. The population was 198,718 in 1870; 198,357 in 1880; 193,580 in 1888; and

206,460 in 1900, being 381 to each square mile. The population is almost exclusively German-speaking; for in 1900 there were but 826 French-speaking, and 2468 Italian-speaking inhabitants. In 1888 there were 85,835 Romanists, 106,351 Protestants, 1051 Jews; in 1900, 91,047 Romanists, 114,218 Protestants, 1010 Jews. The capital is Aarau, the only other towns in the canton which in 1888 had over 3000 inhabitants being Baden, Zofingen (4450), and Reinach (3130). The cantonal constitution dates from 1885. The legislature consists of members elected in the proportion of one to every 1100 (or fraction over 550) inhabitants. The "obligatory referendum" exists in the case of all laws, while 5000 citizens have the right of "initiative" in proposing bills or alterations in the cantonal constitution. The canton sends ten members to the Federal National Assembly, being one for every 20,000, or fraction over 10,000 inhabitants. In 1897 the state revenue was 3,260,156 francs, and the state expenditure 3,064,181 francs, but both in 1898 and in 1899 there was a deficit, while another of 98,600 francs was in the budget of 1900. In 1897 the public debt was 2,430,000 francs, while the productive state property amounted to 19,317,644 francs. There are many old historical castles in Aargau, such as Habsburg, Lenzburg, Wildegg, &c. In 1841 Aargau, under the influence of Augustine Keller, suppressed the eight monasteries (of which the most important were Muri and Wettingen) within its territory, this violent act ultimately leading up to the "Sonderbund" war in Switzerland in 1847.

See *Argovia* (published by the Cantonal Historical Society), Aarau, from 1860.—BRONNER. *Der Kanton Aargau*. 2 vols. St Gall and Bern, 1844.—MERZ. *Die Rechtsquellen d. Kant. Aargau*, 2 vols. as yet. Aarau, 1898 and 1900.—MÜLLER. *Der Aargau*. 2 vols. Zürich, 1870.

Aarhus, a seaport and bishop's see of Denmark, co. Aarhus, on the E. coast of Jutland, 68 miles by rail N. by E. from Fredericia; the second largest town of the kingdom and the principal port of Jutland. There are two new churches—St Paul's (1885-86) and a Roman

Catholic church (1878-81)—a library (1899), and a theatre (1899). A new harbour basin was made in 1883-90. In 1899 the port was entered by 2711 vessels of 476,439 tons, and cleared by 2710 of 476,380 tons; exports, chiefly agricultural produce (bacon, butter, eggs), coal (162,350 tons), iron, and manure. Pop. 24,831 (1880); 33,306 (1890); 43,000 (official estimate, 1898).

Aasen, Ivar (1813-1896), Norwegian philologist and lexicographer, was born at Aasen i Ørsten, in Søndmøre, Norway, on the 5th of August 1813. His father, a small peasant-farmer named Ivar Jonsson, died in 1826. He was brought up to farmwork, but he assiduously cultivated all his leisure in reading, and when he was eighteen he opened an elementary school in his native parish. In 1833 he entered the household of H. C. Thoresen, the husband of the eminent writer Magdalene Thoresen, in Herø, and here he picked up the elements of Latin. Gradually, and by dint of infinite patience and concentration, the young peasant became master of many languages, and began the scientific study of their structure. About 1841 he had freed himself from all the burden of manual labour, and could occupy his thoughts with the dialect of his native district, the Søndmøre; his first publication was a small collection of folk-songs in the Søndmøre language, 1843. His remarkable abilities now attracted general attention, and he was helped to continue his studies undisturbed. His *Grammar of the Norwegian Dialects*, 1848, was the result of much labour, and of journeys taken to every part of the country. Aasen's famous *Dictionary of the Norwegian Dialects* appeared in its original form in 1850, and from this publication dates all the wide cultivation of the popular language in Norwegian, since Aasen really did no less than construct, out of the different materials at his disposal, a popular language or definite *folke-maal* for Norway. With certain modifications, the most important of which were introduced later by Aasen himself, this artificial language is that which has been adopted ever since by those who write in dialect, and which fanatics to-day (1901) are once more endeavouring to foist upon Norway as her official language in the place of Dano-Norwegian. Aasen composed poems and plays in the composite dialect to show how it should be used; one of these dramas, *The Heir* (1855), was frequently acted, and may be considered as the pioneer of all the abundant dialect-literature of the last half-century, from Vinje down to Garborg. Aasen continued to enlarge and improve his grammars and his dictionary. He lived very quietly in lodgings in Christiania, surrounded by his books and shrinking from publicity, but his name grew into wide political favour as his ideas about the language of the peasants became more and more the watchword of the popular party. Quite early in his career, 1842, he had begun to receive a stipend to enable him to give his entire attention to his philological investigations; and the Storting—conscious of the national importance of his work—treated him in this respect with more and more generosity as he advanced in years. He continued his investigations to the last, but it may be said that, after the 1873 edition of his *Dictionary*, he added but little to his stores. Ivar Aasen holds perhaps an isolated place in literary history as the one man who has invented, or at least selected and constructed, a language which has pleased so many thousands of his countrymen that they have accepted it for their schools, their sermons, and their songs. He died in Christiania on the 23rd of September 1896, and was buried with public honours.

(E. G.)

Abádeh, a small walled town in the province of Fars in Persia, situated at an elevation of 6200 feet in a fertile plain on the high road between Isfahan and Shiraz,

140 miles from the former and 170 miles from the latter place. It has a population of about 4000, is the chief place of a district with the same name, has a telegraph and post office, and is famed for its beautifully-carved sherbet spoons and boxes, which are made from the wood of pear and box-trees.

Abai, lake. See ABYSSINIA.

Abai, river. See ABYSSINIA.

Abakan, Abakansk. See MINUSINSK.

Abánah, or AMANAH (R.V. *Abána*, classical *Chrysorrhœas*, modern *Baradd*), one of the "rivers of Damascus," which rises in the heart of Anti-Lebanon. As the river escapes from the mountains, through a narrow gorge, its waters spread out fan-like, in canals or "rivers," to irrigate the plain and supply Damascus. The name of one "river," Nahr Báníás, retains a trace of Abánah; and, in the Arabic translation of O.T., that of another, Nahr Taúra, takes the place of Pharpar, which is identified by some authorities with the Nahr el-'Awaj.

Abattoir. See SLAUGHTER-HOUSES.

Abbadie, Antoine Thomson d' (1810-1897), and **Arnaud Michel d'** (1815-1893), two brothers notable for their travels in Abyssinia during the first half of the 19th century. They were both born in Dublin, of a French father and an Irish mother, the former in 1810 and the latter in 1815. The parents removed to France in 1818, and there the brothers received a careful scientific education. In 1835 the French Academy sent Antoine on a scientific mission to Brazil, the results of which were published at a later date (1873) under the title of *Observations relatives à la physique du globe faites au Brésil et en Éthiopie*. The younger spent some time in Algeria before, in 1837, the two brothers started for Abyssinia, landing at Massawa in February 1838. They visited various parts of Abyssinia, sometimes together, and sometimes separately; not only the fairly well-known northern and central districts, but also the then little-known districts of Ennarea and Kaffa. They met with many difficulties and many adventures, and became involved in political intrigues, Antoine especially exercising such influence as he possessed in favour of France and the Roman Catholic missionaries. After collecting much valuable information concerning the geography, geology, archæology, and natural history of Abyssinia, the brothers returned to France in 1848 and began to prepare their materials for publication. The younger brother, Arnaud, paid another visit to Abyssinia in 1853. The more distinguished brother, Antoine, became involved in various controversies relating both to his geographical results and his political intrigues. He was especially attacked by Dr Beke, who impugned his veracity, especially with reference to the journey to Kaffa. But time and the investigations of subsequent explorers have shown that Abbadie was quite trustworthy. The topographical results of his explorations were published in Paris in 1860-73 in *Géodésie d'Éthiopie*, full of the most valuable information and illustrated by ten maps. Of the *Géographie de l'Éthiopie* (Paris, 1890) only one volume has been published. In *Un catalogue raisonné de manuscrits Éthiopiens* (Paris, 1859) is a description of 234 Ethiopian manuscripts collected by Antoine. He also compiled various vocabularies, including a *Dictionnaire de la langue amarinna* (Paris, 1881), and prepared an edition of the *Pastor of Hermes*, with the Latin version, in 1860. He published numerous papers dealing with the geography of Abyssinia, Ethiopian coins, and ancient inscriptions. Under the title of *Reconnaissances Magné-*

tiques, he published in 1890 an account of the magnetic observations made by him in the course of several journeys to the Red Sea and the Levant. The general account of the travels of the two brothers was published by Arnaud in 1868 under the title of *Douze ans dans la Haute-Éthiopie*. Both brothers received the grand medal of the Paris Geographical Society in 1850. Antoine was a Knight of the Legion of Honour and a member of the Academy of Sciences. He died in 1897, and, subject to the life-interest of his wife, bequeathed an estate in the Pyrenees, yielding 40,000 francs a year, to the Academy of Sciences, on condition of its producing within fifty years a catalogue of half-a-million stars. His brother Arnaud died in 1893.

(J. S. K.)

Abbas II., KHEDIVE OF EGYPT.—Abbas Helmi Pasha, born in 1874, succeeded his father, Tewfik Pasha, as Khedive of Egypt in 1892. He was barely of age according to the Turkish law, which fixes majority at eighteen in cases of succession to the throne. He came straight from his college at Vienna to Cairo, where his accession was celebrated with great pomp, and the firman from the Sultan confirming him in all the powers and privileges and territorial rights which his father enjoyed was read from the steps of the Palace in Abdin Square. He is the great-great-grandson of Mehemet Ali, the founder of the present Egyptian dynasty. When quite a boy he visited England, and did not see it again until he paid a viceregal visit in 1899. He had an English tutor for some time in Cairo, and then went to school in Lausanne, and, from there he passed on to the Theresianum in Vienna, whence he was called to the throne by the premature and sudden death of his father. Turkish is his mother tongue, but he talks Arabic with great fluency and speaks English, French, and German very well. For some time he did not co-operate very cordially with Great Britain. He was young and eager to exercise his new power. His throne and life had not been saved for him by the British, as was the case with his father. He was surrounded by intriguers who were playing a game of their own, and for some time he appeared almost disposed to be as reactionary as his great-uncle, Abbas I. But in process of time he learnt to understand the importance of British counsels. During his visit to England in 1899 he frankly acknowledged the great good the British had done in Egypt, and declared himself ready to follow their advice and to co-operate with the British officials administering Egyptian affairs. The establishment of a sound system of native justice, the great remission of taxation, the reconquest of the Soudan, the inauguration of the stupendous irrigation works at Assouan, the increase of cheap, sound education, have each received his approval and all the assistance he could give. The waters of oblivion cover the quarrel, based on unfounded accusations, which he chose to have with Sir H. (afterwards Lord) Kitchener when that general was Commander-in-Chief of the Egyptian army; and no one more than the Khedive rejoiced over the battle of Omdurman. Agriculture and all the interests of farming are dearer to the heart of the Khedive than statecraft. At Koubah, near Cairo, he has a farm of cattle and horses that would do credit to any agricultural show in England, and at Montaza, near Alexandria, he has a similar establishment. He rides well, drives well, rises early, neither smokes nor drinks. The Vice-Reine or Khediviah, his wife, has given him first a daughter and then a son, and the latter is the heir to the throne.

Abbas-Tuman, a spa situated in Caucasia, government of Tiflis, on a mountain road of Akhaltsykh, 50 miles from the Borzhom railway station, very pictu-

resquely situated at an altitude of 4413 feet. It has a high-level astronomical observatory.

Abbazia, a popular summer and winter resort on the Gulf of Fiume, in the Austrian province of Istria, in a sheltered situation at the foot of the Monte Maggiore. The average temperature is 77° in summer and 50° in winter. The old abbey, from which the place derives its name, has been converted into a villa. Local population (1890), 1192; (1900), 2343.

Abbeville, chief town of arrondissement, in the department of Somme, France, 28 miles N.W. of Amiens, on railway from Paris to Boulogne and Calais. It is a very important industrial centre; and, in addition to its old-established textile productions, hemp-spinning, sugar-manufacture, and ship-building are among the industries, and there is active commerce in grain and textile fabrics. Population (1881), 18,065; (1891), 18,022; (1896), 19,669.

Abbiategrosso, a town of Lombardy, prov. Milan, Italy, 17 miles S.W. from Milan on the Bereguardo Canal. It is the seat of one of the new commercial courts of arbitration of the prov. of Milan. Population, 7025 (1881); 12,184 (1901).

Abbot, Ezra (1819-1884), American biblical scholar, was born in Jackson, Maine, 28th April 1819. He graduated at Bowdoin College in 1840; was appointed assistant librarian of Harvard University in 1856; and in 1872 became professor of New Testament criticism and interpretation in the divinity school of the same institution. For some time previously his studies had been chiefly in Oriental languages and the textual criticism of the New Testament, though his work as a bibliographer had shown such results as the exhaustive list of writings (5300 in all) on the doctrine of the Future Life, appended to W. R. Alger's work on that subject. His publications, though always of the most thorough and most scholarly character, were to a large extent dispersed in the pages of reviews, dictionaries, concordances, texts edited by others, Unitarian controversial treatises, &c.; but he took a more conspicuous and more personal part in the preparation (with the Baptist scholar Horatio B. Hackett) of the enlarged American edition of Dr (afterward Sir) William Smith's *Dictionary of the Bible* (1867-70), and was an efficient member of the American revision committee employed in connexion with the Revised Version (1881-1885) of the King James Bible. His principal single production, representing his scholarly method and conservative conclusions, was *The Authorship of the Fourth Gospel; External Evidences* (1880; second edition, with other essays, 1888), deemed by Dr Philip Schaff and other scholars the ablest defence, based on external evidence, of the Johannean authorship. Abbot, though a layman, received the degree of D.D. from Harvard in 1872. He died in Cambridge, Massachusetts, 21st March 1884.

Abbott, Edwin Abbott, D.D. (1838—), English theological writer, educationalist, and scholar, formerly headmaster of the City of London school, son of the late Edwin Abbott, headmaster of the philological school, Marylebone, was born 20th December 1838. He was educated at the City of London school and at Cambridge, where he took the highest honours in the classical, mathematical, and theological triposes (senior classic, Chancellor's medallist, and senior optime, 1861; 1st cl. Theology, 1862), and became fellow of his College (St John's). In 1862 he was ordained, taking priest's orders in 1863. After holding masterships at King Edward's School, Birmingham, and at Clifton College, he succeeded

Dr Mortimer as headmaster of the City of London school in 1865 at the unusually early age of twenty-six, and more than maintained the high character which the school had obtained under his predecessor. He retired in 1889, and has since devoted himself to literary and theological pursuits. Dr Abbott's liberal inclinations in theology have been prominent both in his educational views and in his books. He has written several works on grammar, both English and Latin, and is the author of a life of Bacon (1885) and of an investigation of his relations with Essex (1877). Of his theological writings (which include some that have been published anonymously) the best known are his religious romances—*Philochristus* (1878) and *Onesimus* (1882), *The Kernel and the Husk* (1886), *Philomythus* (1891), his criticism on *Cardinal Newman as an Anglican* (1892), and his article on "The Gospels" in the ninth edition of the *Encyclopædia Britannica*.

Abbott, Jacob (1803-1879), a popular American writer of books for the young, was born in Hallowell, Maine, on the 14th of November 1803. He graduated at Bowdoin College at the age of seventeen; studied at Andover Theological Seminary; became a congregational minister; was for a brief period professor of mathematics and physics in Amherst College; and afterwards taught in schools at New York and Farmington, Maine, though devoting himself chiefly to the writing of juvenile stories, brief histories and biographies, or religious books for the general reader, together with a few works in popular science. His "Rollo Books"—*Rollo at Work, Rollo at Play, Rollo in Europe*, &c.—are the best known of his writings, having as their chief characters a representative boy and his associates. In them Abbott did for one or two generations of young American readers a service not unlike that performed earlier, in England and America, by the authors of *Evenings at Home, Sandford and Merton*, and the *Parent's Assistant*. Of his other writings—he produced more than two hundred volumes in all—the best are the *Franconia Stories*, a long series of biographical histories (with his brother John S. C. Abbott), and *The Young Christian*. Their merits are interestingness and clearness of statement; their faults a prevalent didacticism, and, in the histories, a superficial treatment of authorities, perhaps necessitated by the great range of ground covered by the author. He died at Farmington on the 31st of October 1879.

Abbott, John Stevens Cabot (1805-1877), American writer, was born in Brunswick, Maine, 18th September 1805. He was a brother of Jacob Abbott, and was associated with him in the preparation of his series of brief historical biographies, but is best known as the author of a partisan and unscholarly, but widely popular and very readable, *History of Napoleon Bonaparte* (1855), in which the various elements and episodes in Napoleon's career are treated with some skill in arrangement, but with unfailing adulation. Like his brother, Dr Abbott was a graduate of Bowdoin College, a congregational minister, a teacher, and a voluminous writer of books on Christian ethics, &c., though he never attempted the fictitious story for children. He died at Fair Haven, Conn., on the 17th of June 1877.

Abbottabad, a town of British India, 4166 feet above sea-level, 63 miles from Rawal Pindi, the headquarters of the Hazara district in the Punjab, called after its founder, Sir James Abbott, who settled this wild district after the annexation of the Punjab. It is an important military cantonment, with two native infantry regiments and a mountain battery; and the headquarters of the Punjab frontier force. Nearest

railway station, Hasan Abdul (44 miles). Population, about 10,000. Municipal income (1896-97), Rs.13,588.

Abd-el-Kader (1807-1883), EMIR OF MASCARA, the most prominent representative of Mussulman resistance to French conquest in Algeria, was born at Mascara, an Arab town between 40 and 50 miles south-east of Oran, in 1807. His family was of princely rank, and he received the best education attainable, especially in Mahomedan divinity and philosophy. Two incidents of his youth had great influence upon his career,—his pilgrimage to Mecca, which stimulated his natural tendency to religious enthusiasm, and a visit to Egypt, where the reforms of Mehemet Ali opened his eyes to the importance of European culture. He was thus doubly prepared for the part he was called upon to perform on the French conquest of Algiers in 1830. Becoming emir of Mascara by the renunciation of his father, he carried on war with the French until 1834, when peace was concluded; but Abd-el-Kader's endeavours to reorganize his principality on a European model excited the jealousy of the French, and war again broke out in the following year. Mascara was taken in October 1835, but the contest on the whole was unfavourable to the French, and peace was eventually made in 1837, on terms highly honourable to Abd-el-Kader. He nevertheless imprudently recommenced the struggle in 1839, and although his capital was again taken in 1841, protracted it until 1844, when he was compelled to seek refuge in Morocco. The French under Marshal Bugeaud crossed the frontier, and in June entirely defeated the Moorish army at Isly, thus virtually ending the Arab revolt. The sultan, though compelled to make peace, continued to give Abd-el-Kader an asylum as long as possible; but early in 1847 the latter re-entered Algeria, and was made prisoner. In violation, as alleged, of the terms of surrender, he was detained a captive in France until 1852, when he was released by Louis Napoleon. He resided successively at Broussa and at Damascus, where in 1860 he rendered such service in repressing an outbreak against the Christians that he received the insignia of the Legion of Honour. In his latter years he devoted himself anew to theology and philosophy, and composed a philosophical treatise which has been translated into French. He died at Damascus 26th May 1883. Abd-el-Kader was an example of all the bright, and few or none of the less prepossessing, traits of the Arab national character. (R. G.)

Abdul-Aziz, SULTAN OF TURKEY (1830-1876), the second son of the great Turkish reformer Sultan Mahmud, was born 9th February 1830. During the reign of his brother Abdul-Medjid he lived in complete retirement, but upon his accession to the throne (25th June 1861) he manifested a reforming spirit and a disposition to economize in personal expenses, and to bring the administration into harmony with the ideas of European culture. Unfortunately, his extravagant outlay on the army greatly overbalanced the economies effected elsewhere, and years of ruinous loan-raising culminated in national bankruptcy in 1875. Before this event, the sultan's mind had been almost entirely given to a project for securing the succession to his son Izeddin, to the prejudice of his nephew Murad, and in pursuit of this object he had thrown himself into the arms of Russia. Financial disaster combined with Russian preponderance rendered his government intolerable; a movement instigated by the principal pashas compelled his abdication on 30th May 1876, and on 4th June he was stated to have committed suicide. Abdul-Aziz was a violent and obstinate man, of great and not always ill-directed energy,

but of narrow intellect, and was probably not entirely sane during the last years of his life.

Abdul Aziz, SULTAN OF MOROCCO, is the son of Sultan Mulaï-Hassan. He was born about 1881, and succeeded to the throne on the death of his father, 7th June 1894, being proclaimed sultan in the Sherifian camp on the 11th of the same month. In the following October he received the British mission, under Sir Ernest Satow, with the utmost cordiality at Fez, and a convention was signed in April 1895. The sultan has proved constant in his friendship to Great Britain, and welcomed Sir Arthur Nicholson, the British minister, in 1896. In the following year he made a vigorous campaign against the Riffians and others of his disaffected subjects, and overthrew them completely at Tadra, in October 1897.

Abdul-Hamid II., SULTAN OF TURKEY, is the second son of Sultan Abdul-Medjid, who reigned from 1839 to 1861. He was born 22nd September 1842, and succeeded on 31st August 1876, on the deposition of his brother Murad on the ground of insanity. His position at the time was very difficult, and he feigned sympathy at first with the policy of reform advocated by progressive officials such as Midhat Pasha. The revolt of the Christian subjects of the Porte in European Turkey, and the barbarous methods adopted to quench Bulgarian disaffection, equally played into the hands of Russia; and though, during the Russo-Turkish war (1877-78), the military virtues of the Turkish soldier and the gallant defence of Plevna restored a large measure of sympathy to Turkey, the treaties of San Stefano and of Berlin marked a further stage in the dismemberment of the Ottoman empire. As soon as the war was over, Abdul Hamid began to apply himself, with equal dexterity and persistency, to two great objects, viz., the substitution of his own personal authority for that of the great bureaucracy which had ruled Turkey under his immediate predecessors from the Sublime Porte, and the extension of his influence as spiritual sovereign or Kalif in compensation for the loss of temporal power inflicted upon the sultanate. To establish his autocracy he did not shrink from sacrificing all the ablest men in his empire. His external policy was scarcely less successful and less unscrupulous. His dexterous diplomacy played off one great Power against another, and enabled him even to escape the storm which threatened at one moment to overwhelm him, when public opinion in Europe, and especially in England, realized the horror of the Armenian massacres in 1896. Russia secretly, and Germany openly, discountenanced Lord Salisbury's efforts to secure the united action of Europe, and the Cretan insurrection soon diverted the attention of diplomacy to another quarter. The successful war with Greece in 1897 did much to revive Turkish military prestige; and the practical loss of Crete, although evincing the decay into which the Turkish navy had been allowed to fall, rather increased than diminished the strength of the empire. Perhaps the most important feature in Abdul-Hamid's later policy has been the disposition shown to rely upon Germany, and to grant that Power special privileges in Asia Minor.

For a fuller account of his reign, see TURKEY, ARMENIA, CRETE, BULGARIA, &c.

Abdullah Khalifa (SAYED ABDULLAH IBU-SAYED MOHAMMED), (1846-1899), successor of the Mahdi Mohammed Ahmed, was born in 1846 in the south-western portion of Darfur, and belonged to the Taaisha section of the Baggaras or cattle-owning Arabs. His father, Mohammed et Tabis, had determined to emigrate to Mecca with his family; but the unsettled state of the country long prevented him, and he died in Africa after

advising his eldest son, Abdullah, to take refuge with some religious sheikh on the Nile, and to proceed to Mecca on a favourable opportunity. Abdullah, who had already had much connexion with slave-hunters, and had fought against the Egyptian conquest of Darfur, departed for the Nile valley with this purpose; but, hearing on the way of the disputes of Mohammed Ahmed, who had not yet claimed a sacred character, with the Egyptian officials, he went to him in spite of great difficulties, and, according to his own statement, at once recognized in him the Mahdi ("Director") divinely appointed to regenerate Islam in the latter days. His advice to Mohammed to stir up revolt in Darfur and Kordofan being justified by the result, he became his most trusted counsellor, and was soon declared khalifa or vicegerent of the Mahdi, all of whose acts were to be regarded as the Mahdi's own. The Mahdi on his death-bed (1885) solemnly named him his successor; and for many years Abdullah, though to European ideas a monster of cruelty, injustice, and hypocrisy, ruled successfully over the Sudan, with little opposition from within, and extending his sway over neighbouring districts. Khartum was deserted by his orders, and Omdurman, at first intended as a temporary camp, was made his capital. At length the progress of Sir H. (afterwards Lord) Kitchener's expedition compelled him to give battle to the Anglo-Egyptian forces near Omdurman, where on 2nd September 1898 his army, fighting with desperate courage, was almost annihilated. He fled to the north, but want of provisions in the following year compelled him to venture too near the army of Sir Francis Wingate, by whom, at the end of November 1899, he was overtaken and slain at the battle of Om Dehrihat. He met death with great fortitude, refusing to fly, and his principal emirs voluntarily perished with him.

(R. G.)

Abdurrahman Khan, AMIR OF KABUL (Afghanistan), (circa 1844-1901), was the son of Afzul Khan, who was the eldest son of Dost Mahommed Khan, the famous Amir, by whose success in war the Barakzaie family established their dynasty in the rulership of Afghanistan. Before his death at Herat, 9th June 1863, Dost Mahommed had nominated as his successor Sher Ali, his third son, passing over the two elder brothers, Afzul Khan and Azim Khan; and at first the new Amir was quietly recognized. But after a few months Afzul Khan raised an insurrection in the northern province, between the Hindu Kush mountains and the Oxus, where he had been governing when his father died; and then began a fierce contest for power among the sons of Dost Mahommed, which lasted for nearly five years. In this war, which resembles in character, and in its striking vicissitudes, the English War of the Roses at the end of the 15th century, Abdurrahman soon became distinguished for ability and daring energy. Although his father, Afzul Khan, who had none of these qualities, came to terms with the Amir Sher Ali, the son's behaviour in the northern province soon excited the Amir's suspicion, and Abdurrahman, when he was summoned to Kabul, fled across the Oxus into Bokhara. Sher Ali threw Afzul Khan into prison, and a serious revolt followed in South Afghanistan; but the Amir had scarcely suppressed it, by winning a desperate battle, when Abdurrahman's reappearance in the north was a signal for a mutiny of the troops stationed in those parts, and a gathering of armed bands to his standard. After some delay and desultory fighting, he and his uncle, Azim Khan, occupied Kabul (March 1866). The Amir Sher Ali marched up against them from Kandahar; but in the battle that ensued at Shekhabad on 10th May he was

deserted by a large body of his troops, and after his signal defeat Abdurrahman released his father, Afzul Khan, from prison in Ghazni, and installed him upon the throne as Amir of Afghanistan. Notwithstanding the new Amir's incapacity, and some jealousy between the real leaders, Abdurrahman and his uncle, they again routed Sher Ali's forces, and occupied Kandahar in 1867; and when at the end of that year Afzul Khan died, Azim Khan succeeded to the rulership, with Abdurrahman as his governor in the northern province. But towards the end of 1868 Sher Ali's return, and a general rising in his favour, resulting in their defeat at Tinah Khan on January 3, 1869, forced them both to seek refuge in Persia, whence Abdurrahman proceeded afterwards to place himself under Russian protection at Samarkhand. Azim died in Persia in October 1869.

This brief account of the conspicuous part taken by Abdurrahman in an eventful war, at the beginning of which he was not more than twenty years old, has been given to show the rough school that brought out his qualities of resource and fortitude, and the political capacity needed for rulership in Afghanistan. He lived in exile for eleven years, until on the death, in 1879, of Sher Ali, who had retired from Kabul when the British armies entered Afghanistan, the Russian Governor-General at Tashkend sent for Abdurrahman, and pressed him to try his fortunes once more across the Oxus. In March 1880 a report reached India that he was in northern Afghanistan; and the Governor-General, Lord Lytton, opened communications with him to the effect that the British Government were prepared to withdraw their troops, and to recognize Abdurrahman as Amir of Afghanistan, with the exception of Kandahar and some districts adjacent. After some negotiations, an interview took place between him and Mr (afterwards Sir) Lepel Griffin, the diplomatic representative at Kabul of the Indian Government, who described Abdurrahman as a man of middle height, with an exceedingly intelligent face, and frank and courteous manners, shrewd and able in conversation on the business in hand. At the durbar on 22nd July 1880, Abdurrahman was officially recognized as Amir, granted assistance in arms and money, and promised, in case of unprovoked foreign aggression, such further aid as might be necessary to repel it, provided that he followed British advice in regard to his external relations. The evacuation of Afghanistan was settled on the terms proposed, and in 1881 the British troops also made over Kandahar to the new Amir; but Ayub Khan, one of Sher Ali's sons, marched upon that city from Herat, defeated Abdurrahman's troops, and occupied the place in July. This serious reverse roused the Amir, who had not at first displayed much activity. He led a force from Kabul, met Ayub's army close to Kandahar, and the complete victory which he there won forced Ayub Khan to fly into Persia. From that time Abdurrahman was fairly seated on the throne at Kabul, and in the course of the next few years he consolidated his dominion over all Afghanistan, suppressing insurrections by a sharp and relentless use of his despotic authority. Against the severity of his measures the powerful Ghilzaie tribe revolted, and were crushed by the end of 1887. In that year Ayub Khan made a fruitless inroad from Persia; and in 1888 the Amir's cousin, Ishak Khan, rebelled against him in the north; but these two enterprises came to nothing.

In 1885, at the moment when (see AFGHANISTAN) the Amir was in conference with the British Viceroy, Lord Dufferin, in India, the news came of a collision between Russian and Afghan troops at Panjdeh, over a disputed point in the demarcation of the north-western frontier of Afghanistan. Abdurrahman's attitude at this critical

junction is a good example of his political sagacity. To one who had been a man of war from his youth up, who had won and lost many fights, the rout of a detachment and the forcible seizure of some debateable frontier lands was an untoward incident; but it was no sufficient reason for calling upon the British, although they had guaranteed his territory's integrity, to vindicate his rights by hostilities which would certainly bring upon him a Russian invasion from the north, and would compel his British allies to throw an army into Afghanistan from the south-east. His interest lay in keeping powerful neighbours, whether friends or foes, outside his kingdom. He knew this to be the only policy that would be supported by the Afghan nation; and although for some time a rupture with Russia seemed imminent, while the Indian Government made ready for that contingency, the Amir's reserved and circumspect tone in the consultations with him helped to turn the balance between peace and war, and substantially conduced towards a pacific solution. Abdurrahman left on those who met him in India the impression of a clear-headed man of action, with great self-reliance and hardihood, not without indications of the implacable severity that has too often marked his administration. His investment with the insignia of the highest grade of the Order of the Star of India appeared to give him much pleasure.

From the end of 1888 the Amir passed eighteen months in his northern provinces bordering upon the Oxus, where he was engaged in pacifying the country that had been disturbed by revolts, and in punishing with a heavy hand all who were known or suspected to have taken any part in rebellion. Shortly afterwards (1892) he succeeded in finally beating down the resistance of the Hazara tribe, who vainly attempted to defend their immemorial independence, within their highlands, of the central authority at Kabul.

In 1893 Sir Henry Durand was deputed to Kabul by the Government of India for the purpose of settling an exchange of territory required by the demarcation of the boundary between north-eastern Afghanistan and the Russian possessions, and in order to discuss with the Amir other pending questions. The Amir showed his usual ability in diplomatic argument, his tenacity where his own views or claims were in debate, with a sure underlying insight into the real situation. The territorial exchanges were amicably agreed upon; the relations between the Indian and Afghan Governments, as previously arranged, were confirmed; and an understanding was reached upon the important and difficult subject of the border line of Afghanistan on the east, towards India. In 1895 the Amir found himself unable, by reason of ill-health, to accept an invitation from Queen Victoria to visit England, but his second son Nasrulla Khan went in his stead.

Abdurrahman died on the 1st October 1901, being succeeded by his son Habibulla. He had defeated all enterprises by rivals against his throne; he had broken down the power of local chiefs, and tamed the refractory tribes; so that his orders were irresistible throughout the whole dominion. His government was a military despotism resting upon a well-appointed army; it was administered through officials absolutely subservient to an inflexible will, and controlled by a widespread system of espionage; while the exercise of his personal authority was too often stained by acts of unnecessary cruelty. He held open courts for the receipt of petitioners and the dispensation of justice; and in the disposal of business he was indefatigable. He succeeded in imposing an organized government upon the fiercest and most unruly population in Asia; he availed himself of European inventions for strengthening his armament, while he sternly set

his face against all innovations which, like railways and telegraphs, might give Europeans a foothold within his country. His adventurous life, his forcible character, the position of his State as a barrier between the Indian and the Russian empires, and the skill with which he held the balance in dealing with them, combined to make him a prominent figure in contemporary Asiatic politics, and will mark his reign as an epoch in the history of Afghanistan.

The Amir received an annual subsidy from the British Government of 18½ lakhs of rupees. He was allowed to import munitions of war. In 1896 he adopted the title of *Zia-ul-Millat-ud-Din* (Light of the nation and religion); and his zeal for the cause of Islam induced him to publish treatises on Jihad. His eldest son Habibulla Khan, with his brother Nasrulla Khan, was born at Samarkhand. His youngest son, Mahommed Umar Jan, was born in 1889 of an Afghan mother, connected by descent with the Barakzaie family.

Abel, Sir Frederick Augustus, BART. (1827—), English chemist, was born in London, 17th July 1827. Determining to adopt chemistry as his profession, he was one of the first students to enter the Royal College of Chemistry, which was established in 1845 under the direction of the distinguished German chemist, von Hofmann. After remaining there for six years, during five of which he acted as one of Hofmann's assistants, he became Professor of Chemistry at the Royal Military Academy in 1851, and three years later was appointed Chemist to the War Department and Chemical Referee to the Government. During his tenure of this office, which lasted until 1888, he carried out a large amount of work in connexion with the chemistry of explosives, one of the most important of his investigations having to do with the manufacture of gun-cotton. Continuing and supplementing the work of Lenk in Austria, he devised a process which enabled it to be prepared with practically no danger, and which at the same time yielded the product in a form that increased its usefulness. This consisted essentially in reducing the cotton, after nitration, to fine pulp. A double advantage was thereby gained; the material could be more certainly washed free from every trace of the acid which, if not removed, renders it liable to spontaneous combustion, while control over the rate of explosion, which is largely a question of mechanical condition, could be gained by hydraulic compression of the pulp into masses of whatever size and shape might be found desirable. These improvements in the manufacture of gun-cotton contributed in an important degree to the preparation of the smokeless powders, which in the latter part of the 19th century came into general use for military purposes all over the world. Cordite, the particular form adopted by the British Government, was the joint invention of Abel and Professor Dewar, who, with Dr Dupré, constituted the special Committee on Explosives which sat from 1888 to 1891 to select a smokeless powder for the British army and navy. For his services as chairman of this committee Abel was made a K.C.B. Our knowledge of the explosion of ordinary black powder was also greatly added to by him, and in conjunction with Sir A. Noble he carried out one of the most complete inquiries on record into its behaviour when fired. The invention of the apparatus, legalized in 1879, for the determination of the flash-point of petroleum, was another piece of work which fell to him by virtue of his official position. His first instrument, the open-test apparatus, was prescribed by the Act of 1868, but, being found to

possess certain defects, it was superseded in 1879 by the Abel close-test instrument. The earlier Act imposed restrictions on the storage of petroleum having a flash-point below 100° F., as ascertained by the open-test instrument, and by the second one it was intended to maintain the same standard. It therefore became necessary to ascertain the relation between the two tests, and for this purpose Abel superintended a long series of experiments, which showed that, on the average, oil which flashed at 100° open-test flashed at only 73° close-test. The latter figure was therefore legalized as the equivalent of the former under the new conditions. Abel's researches were not confined to chemistry. In electricity he studied the construction of electrical fuzes and other applications of that form of energy to warlike purposes, and in 1877 he served as president of the Institution of Electrical Engineers (then the Society of Telegraph Engineers). Problems of steel manufacture also engaged his attention, and in 1891-93 he was president of the Iron and Steel Institute, whose Bessemer medal he was awarded in 1897. Of the Royal Society he became a member in 1860, receiving a Royal medal in 1887. He took an important part in the work of the Inventions Exhibition in 1885, and in 1887 became organizing secretary and first director of the Imperial Institute. Among the books he has published are *Handbook of Chemistry* (with Bloxam), *Modern History of Gunpowder* (1866), *Gun-cotton* (1866), *On Explosive Agents* (1872), *Researches in Explosives* (1875), and *Electricity applied to Explosive Purposes* (1884). He also wrote several important articles in the ninth edition of the *Encyclopædia Britannica*.

Abeokuta. See LAGOS.

Aberavon, a municipal and contributory parliamentary borough and railway station of Glamorganshire, Wales, near the mouth of the Avon, 11 miles E.S.E. of Swansea. It belongs to the Swansea parliamentary district of boroughs. The port of Aberavon is Port Talbot, where there is a dock over a mile long, and from 240 to 900 feet wide. Area of municipal borough, 2060 acres. Population in 1881, 4859; in 1891, 6300; in 1901, 7553.

Abercarn, a large village in the southern parliamentary division of Monmouthshire, England, 10 miles N.W. from Newport by rail. There are collieries and ironworks in the district. The urban district includes part of the civil parish of Mynyddylwyr; area, 9504 acres; population in 1881, 5964; in 1891, 10,464; in 1900, 12,607.

Aberconway. See CONWAY.

Aberdare, a market-town and railway station of Glamorganshire, Wales, 4 miles S.W. of Merthyr Tydfil, of which parliamentary borough it forms part. The town has continued to advance rapidly both in numbers and in general prosperity. The new erections include Established and Presbyterian churches, an infectious diseases hospital, a cottage hospital, a theatre, a memorial hall, a theological college, and a technical and intermediate school; there is also a commodious industrial training school, and the town now possesses two extensive public parks. Besides the prosperous mineral industries, there are brick and pottery works, and several breweries. Population of township in 1881, 35,533; in 1891, 40,917; of urban district in 1891, 38,431; in 1901, 43,357.

Aberdeen, a royal burgh, city, and county of a city (1899), and the county town of Aberdeenshire, Scotland, situated on a bay between the mouths of the rivers Dee and Don, 111 miles N. of Edinburgh by road and 130¼ by rail (Forth Bridge route). The city

has grown and prospered in an exceptional degree during the past half-century, owing to the development of the trawling industry, its educational facilities, and the attractions it offers to residents. In 1883, 900 acres were added to the municipal area, which was further extended in 1891 from 2681 to 6602 acres, incorporating in the city the burghs of Old Aberdeen and Woodside, and the district of Torry on the other side of the Dee. A large number of handsome streets have been laid out, and 200 to 400 buildings have been erected annually at a total estimated cost of £150,000 to £350,000. An esplanade is being laid out along the sea-beach, and a boulevard constructed round the city. Union Terrace Gardens are now public, and Duthie Park (44 acres), lying on the north bank of the Dee, has been opened; it is adorned with a granite statue of Hygeia in honour of the donor. The latest addition to the parks is Stewart Park (13½ acres). By the introduction of a freer treatment of granite the architecture of the city generally has been much improved in recent years. Marischal College has been rendered a still more striking feature of Aberdeen. Under an extension scheme to which the Treasury contributed £40,000, the Town Council £23,350, and one donor between £20,000 and £30,000, a splendid graduation hall has been built, considerable additions have been made to the class-room accommodation, and the edifice has been crowned by a lofty and imposing tower, while the front, long concealed by mean houses, has been largely opened up. King's College also has been extended, and the chapel reconstructed internally and decorated. A botanic garden was presented to the university in 1899, and the opening of the Mitchell Hall coincided with the celebration of the quatercentenary of the university in 1895. Two viaducts carrying streets have been constructed, and Victoria Bridge over the Dee opened. The East church, burned down in 1874, has been rebuilt, and a massive granite tower erected over the aisle connecting it with the West church. This tower has been furnished with a Jubilee peal of 36 bells. The New Market, destroyed by fire in 1882, was rebuilt in 1883. Perhaps the most important of the new public buildings is the Museum and Art Gallery and School of Art (Italian Renaissance in red and brown granites) opened in 1883 and 1884. Other recently erected public buildings are new harbour offices, new fish market, new School Board offices, free library, theatre, Union Club, bathing station, Salvation Army Citadel (on a prominent site), and new Parish Council Chambers. The Royal Infirmary has been largely rebuilt since 1887 as a memorial of Queen Victoria's Jubilee, and Trinity Hall has been extended. St Mary's Chapel has been restored, and a dozen or more new churches have been built within the last few years. A large extension of the railway station was authorized in 1899. New statues are Queen Victoria in bronze (1893), General Gordon (1888), Sir William Wallace (colossal bronze) (1888), and Burns in bronze (1892).

Aberdeen has been represented in Parliament since 1885 by two members, who sit for the north and south divisions. The Town Council has now 34 members, including six magistrates. The two parishes of St Nicholas and old Machar were amalgamated by the Local Government Act of 1894, and the poor law is administered by a parish council of 31 members. The Town Council began in 1899 to work the tramways; one of the routes has been equipped for overhead electric traction. Electric light has been introduced by the Corporation. Extensive improvements of the harbour accommodation have been made, including the construction of a graving dock, which has proved a failure, and is being rebuilt; a bridge across the docks is being constructed. The harbour revenue rose from £32,229 in 1871 to £68,849 in 1899. At the end of 1898, 201 vessels of 96,682 tons were registered at the port, and the movements of shipping were—1888, entered 2706 vessels of 726,886 tons, cleared 2649 vessels of 703,162 tons; 1898, entered 3417 vessels of 936,409 tons, cleared 3349 vessels of 934,175 tons. Imports were valued at £662,102 in 1888 and £927,624 in 1898;

exports £135,382 in 1888 and £145,118 in 1898. The customs revenue at the port averaged £82,384 a-year in 1894-98. The granite industry continues to progress, but the most striking development has been in the fishing industry. Beam-trawling was introduced in 1882, and steam line fishing in 1889. Now there are 83 trawlers registered at the port, and 52 more make Aberdeen their headquarters. These are manned by 1140 men, and the capital invested in boats and gear is estimated at over £700,000. During 1899 there were in all 7700 arrivals. Fifty foreign smacks and luggers made landings during the year. In 1899, 886,037 tons of fish were landed which were valued at £537,422, and of that quantity 687,814 tons of £434,885 were trawl fish. A fresh impetus has been given recently to linen manufacture. Ship-building, which at one time threatened to decay, has been revived by the trawling industry; 11 vessels of 9380 tons were launched in 1889 and 28 vessels of 11,973 in 1899. The university has now 24 professors and 12 lecturers, mostly of recent institution, and its scholarships and bursaries are of £7603 annual value, a bequest of £20,000 for this purpose having been made in 1897. Matriculated students numbered 753 in session 1898-9. Gordon's Hospital was transformed in 1881 into Gordon's College, a day and night secondary school, in which special attention is paid to scientific and secondary education. The grammar school for boys and a high-school for girls are under the School Board, and there are several private higher-class schools. An Educational Trust constituted under the Endowments Act of 1882 possesses a capital of £155,000. Valuation in 1889-90, £650,802; 1890-1900, £753,802. Population in 1881, 105,003; 1891, 121,623; 1901, 153,108.

Aberdeenshire, a maritime county of N.E. Scotland, bounded N. and E. by the German Ocean, S. by the counties of Kincardine and Perth, and W. by Banff and Inverness shires.

Area and Population.—In 1891 the Banffshire portions of the parishes of Gartly, Glass, New Machar, Old Deer, and St Fergus were transferred to Aberdeenshire, and the Aberdeenshire portion of the parish of Cabrach to Banffshire. Of parishes partly in Aberdeen and partly in Kincardine, Drumoak was placed wholly in the former and Banchory-Ternan in the latter county. According to the latest official estimate the area of the county (foreshore excluded), is 1,268,705 acres, or about 1982 square miles. The population was in 1881, 267,990; in 1891, 281,332; in 1891 on the extended area, 284,036, of whom 135,185 were males, and 148,851 females. On the old area, taking land only (1,251,451 acres, or 1955.4 square miles), the number of persons to the square mile in 1891 was 144, and the number of acres to the person 4.4. In the registration county the population increased between 1881 and 1891 by 4.83 per cent. In 1901 the population was 304,420, an increase of 20,384. The following table gives particulars of the births, deaths, and marriages in 1880, 1890, and 1899:—

Year.	Marriages.	Births.	Deaths.	Percentage of Illegitimate.
1880	1700	9099	4472	14.4
1890	1743	8436	5205	12.98
1899	2283	9135	4884	11.2

The birth-rate, death-rate, and marriage-rate were all below the rates for Scotland. The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

	1880.	1881-90.	1890.	1891-98.	1899.
Birth-rate	34.05	32.15	30.02	31.08	31.04
Death-rate	16.73	16.77	18.52	16.72	16.59
Marriage-rate	6.36	6.23	6.20	7.25	7.75

According to the census of 1891 there were in the county 1538 Gaelic-speaking persons, of whom 8 spoke Gaelic only, and there were 204 foreigners. Valuation in 1889-90, £856,173; 1899-1900, £920,246.

Administration.—The county returns two members to Parliament—for the East and West divisions respectively. Besides the county town, Aberdeen (121,623), which returns two members, there are in the county two royal and parliamentary burghs, Inverurie (3105) and Kintore (686), and one parliamentary burgh, Peterhead (12,195), all of which belong to the Elgin group of burghs for parliamentary representation. Important police burghs are Huntly (3760), Fraserburgh (7466), and Turriff (2341). There are 82 civil parishes, 24 of which belong to the Buchan Combination, with a poorhouse at Maud, while the city parish has poorhouses in Aberdeen. The number of paupers and dependants in September 1899 was 6698. The county forms a sheriffdom with Banff and Kincardine, and there are two resident sheriffs—substitute in Aberdeen, who sit also at Peterhead, Fraserburgh, Huntly, and Turriff.

Education.—Ninety-two school boards manage 258 schools, which had an average attendance of 43,388 in 1898-99, while 38 voluntary schools, of which 14 are Episcopal and 6 Roman Catholic, had 5507. There are 3 higher-class schools in Aberdeen, and secondary schools at Huntly, Peterhead, and Fraserburgh, and 69 other schools in the county earned grants in 1898 for giving secondary education. The County Secondary Education Committee dispensed £4253 in 1899, of which £2247 came from the Education Department and £2006 was contributed by local authorities from the "residue" grant, and supported, besides the schools mentioned, local classes and itinerant lectures in agriculture, fishery, and other technical subjects, besides subsidizing the agricultural department of the university of Aberdeen.

Agriculture.—In no county in Scotland has a more productive soil been made out of unpromising material during the 19th century. Oats are the predominant crop, but the barley acreage has been nearly doubled since 1872, while wheat has practically gone out of cultivation. The most distinctive industry is cattle-feeding. A large number of the home-bred crosses are fattened for the London and local markets, and Irish animals are imported on a large scale for the same purpose. An exceedingly large business in the sale of live stock and dead meat is done all over the county, and the average weekly export of dead meat from Aberdeen for the London and southern markets has been estimated at 150 to 200 tons, while the shipment of cattle for the same destinations averages 50 to 70 head weekly. The following table gives the principal acreages at intervals of five years from 1880 :—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Perma- nent Pasture.	Fallow.
1880	603,226	212,767	104,203	259,645	25,861	748
1885	611,424	215,950	102,469	263,004	29,372	626
1890	614,365	213,887	101,243	268,058	30,290	543
1895	630,070	215,730	101,709	276,389	35,711	196
1899	630,121	214,920	100,109	283,968	30,563	184

The following table gives particulars of the live stock during the same years :—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf.	Sheep.	Pigs.
1880	26,851	152,106	41,318	137,693	7,240
1885	25,963	166,003	45,235	158,587	10,761
1890	26,637	163,240	43,261	195,689	12,061
1895	31,114	173,961	43,497	183,951	10,379
1899	30,330	175,407	45,540	232,863	12,346

Aberdeenshire has by far the largest cultivated area of any county in Scotland, and the largest number of holdings, but the percentage of cultivation is only 49.6. Of the 11,567 holdings in 1895, the average size was 54 acres. The percentage under 5 acres was 14.37; between 5 and 50 acres 49.23, and over 50 acres 36.40. Farms between 50 and 100 acres numbered 2164, between 100 and 300, 1912; between 300 and 500, 124, and between 500 and 1000, 10; there were none above 1000 acres. According to the census of 1891 there were 26,386 men and 1213 women engaged in agriculture. The acreage under wood in 1895 was 108,976, of which 7986 had been planted since 1881.

Industries and Trade.—There are now a number of paper-making establishments in the shire, most of them on the Don in the vicinity of Aberdeen. Aberdeen is the premier granite county in the kingdom. There are quarries at Aberdeen, Kemnay, Peterhead, and elsewhere, and the output was 242,168 tons valued

at £132,373 in 1895, and 335,075 tons valued at £176,461 in 1899. Quarrying and dressing the stone gave employment in 1891 to 6294 persons. Fishing, however, is the next most important industry to agriculture. The nineteen ports and creeks of the county are divided into the three fishery districts of Peterhead, Fraserburgh, and Aberdeen, the last of which includes also three Kincardineshire ports. The following table gives statistics of the three districts jointly in 1890, 1898, and 1899 :—

Year.	Boats.			Value of Gear.	Resident Fishermen and Boys.	Total Value of all Fish.
	No.	Tons.	Value.			
1890	1503	18,994	£193,817	£153,695	4822	£556,657
1898	1530	22,306	£497,659	£167,668	3929	£883,129
1899	1436	22,959	£731,534	£164,243	5417	£968,805

The number of persons in the three districts employed in the various branches of the sea fisheries was 21,232 in 1899. Between a half and a third of the catch consists of herrings. The herring season for Aberdeen, Peterhead, and Fraserburgh is from June to September, at which time the ports are crowded with boats from other Scottish districts. The development of the fisheries of late years has been due to the trawlers almost exclusively. (See ABERDEEN.) There are valuable salmon fishings—rod, net, and stake-net—on the Dee, Don, Ythan, and Ugie. The average annual despatch of salmon from Aberdeenshire during the years 1894 to 1898 was about 400 tons. A branch (15½ m.) of the Great North of Scotland Railway was opened in 1897, and a light railway (13 m.) has been sanctioned.

Abergavenny, a municipal borough (1899), market-town, and railway station, in the northern parliamentary division of Monmouthshire, England, at the confluence of the Gavenny and the Usk, 16 miles W. of Monmouth. The lunatic asylum has been enlarged and a cottage hospital built. Population of urban district (borough) in 1891, 7743, on an area of 825 acres; in 1901, 7795; of parish in 1881, 7886; in 1891, 9036.

Aberystwith, a municipal borough, market town, and seaport of Cardiganshire, Wales, at the confluence of the Ystwith and Rheidol, 244 miles from London by rail. It ceased to be a parliamentary borough in 1885. Modern erections are two Established churches, Wesleyan and Welsh Calvinist chapels, a pier pavilion, a ladies' hostel in connexion with the University College of Wales, baths, and a new infirmary. The University College of Wales was opened in 1872, and in 1900 had 31 professors and 474 students. In the town and neighbourhood are engineering works, foundries, and slate-quarries. The corporation is lord of the manor, and owns nearly four-fifths of the town. Population in 1881, 7088; in 1891, 6725; in 1901, 8013. Area, 845 acres.

Abeshr. See WADAI.

Abila, (1) the capital of the tetrarchy of Abilene, was an important town on the imperial highway from Damascus to Heliopolis (*Baalbek*), and is now represented by Sūk Wádi Baradá, a village called by early Arab geographers Ábil es-Súk. The tetrarchy was granted by Caligula, 37 A.D., to Agrippa I., and by Claudius, 52 A.D., to Agrippa II. (2) A city in Perea, now Ábil ez-Zeit.

Abingdon, a municipal borough and market-town in the Abingdon parliamentary division (since 1885) of Berkshire, England, 61 miles W.N.W. of London by rail. The old churches of St Helen and of St Nicholas have been restored, a corn exchange, a cottage hospital, and a

free public library erected, and municipal drainage works and water works executed. The town has important corn markets and horse fairs. Area of borough, 730 acres. Population in 1881, 6755; in 1891, 6557; in 1901, 6480.

Åbo, city and seaport of Finland, Russia, capital of the Abo-Björneborg province; 381 miles by rail from St Petersburg, *via* Tavastehus; in regular steamer communication with St Petersburg, Wasa, and Stockholm. Ship-building has considerably developed lately, warships being built for the Russian navy. This city is only second in Finland to Helsingfors for its trade. Its harbour (Bornholm, on Hyrvinsala Island) is entered yearly by from 700 to 800 ships, of about 200,000 tons. Population, 18,109 in 1867; 34,339 in 1897.

Abo-Björneborg, a province occupying the S.W. corner of Finland, and including the Åland islands. Its population reached 413,351 in 1897, of whom 12 per cent. lived in towns. It occupies the first rank in Finland for its manufactures of cottons, sugar refinery, wooden goods, metals, machinery, paper, &c. Its chief towns are—Abo, Marienhaven (759), Nodendal (654), Nystad (4023), and Raumo (4111).

Abomey. See DAHOMEY.

About, Edmond François Valentin (1828-1885), French novelist, publicist, and journalist, was the son of a grocer, and was born on the 14th of February 1828, at Dieuze, in Lorraine. The boy's school career was brilliant. In 1848 he entered the École Normale, taking the second place in the annual competition for admission, Taine being the first. Among his college contemporaries were Taine, Paul Albert, Weiss, Assolant, Sarcey, Challemeil-Lacour, the ill-starred Prevost-Paradol. Of them all About was, according to Sarcey (*Souvenirs de Jeunesse*), the most highly vitalized, exuberant, brilliant, and "undisciplined." At the end of his college career he joined the French school in Athens, but if we may believe his own account, it had never been his intention to follow the professorial career, for which the École Normale was a preparation, and in 1853 he returned to France and frankly gave himself to literature and journalism. A book on Greece, *La Grèce contemporaine* (1855), which did not spare Greek susceptibilities, had an immediate success. *Tolla*, which remains one of his best novels, appeared shortly after, and during the next few years, with indefatigable energy, and generally with full public recognition, he wrote novels, stories, a play—which failed—a book-pamphlet on the Roman question, many pamphlets on other subjects of the day, newspaper articles innumerable, some art criticisms, rejoinders to the attacks of his enemies, and popular manuals of political economy, *L'A B C du Travailleur*, *Le Progrès*. About's attitude towards the empire was that of a candid friend. He believed in its improvability, greeted the Liberal ministry of Émile Olivier at the beginning of 1870 with delight, and welcomed the Franco-German war. That day of enthusiasm had a terrible morrow. For his own personal part he lost the loved home near Saverne in Alsatia, which he had purchased in 1858, out of the fruits of his earlier literary successes. With the fall of the empire he became a Republican, and, always an inveterate anti-clerical, he threw himself with ardour into the battle against the conservative reaction which made head during the first years of the Republic. From 1872 onwards for some five or six years his paper, the *XIX^e Siècle*, of which he was the heart and soul, became a power in the land. But the Republicans never quite forgave the tardiness of his conversion, and no place rewarded his later zeal. On the 23rd January 1884 he was elected a member of the French Academy, but died on the 26th January 1885, be-

fore taking his seat. Dust has accumulated on the mass of About's work. His journalism—of which specimens in his earlier and later manners will be found in the two series of *Lettres d'un bon jeune homme à sa Cousine Madeleine* (1861 and 1863) and *Le Dix-neuvième Siècle* (1892)—was of its nature ephemeral. So were the pamphlets, great and small. His political economy was that of an orthodox popularizer, and in no sense epoch-making. His dramas are negligible. His more serious novels, *Madelon*, *L'Infâme*, the three that form the series of the *Vieille Roche*, and *Le Roman d'un brave homme*—a kind of counterblast to the view of the French workman presented in M. Zola's *Assommoir*—contain striking and amusing scenes no doubt, but scenes which are often suggestive of the stage, while description, dissertation, explanation too frequently take the place of life. His best work after all is to be found in the books that are almost wholly farcical, *Le nez d'un notaire*, *Le Roi des Montagnes*, *L'Homme à l'oreille cassée*, *Trente et quarante*, *Le Cas de M. Guérin*. Here his most genuine wit, his sprightliness, his vivacity, the fancy that was in him, have free play. "You will never be more than a little Voltaire," said one of his masters when he was a lad at school. It was a true prophecy. (F. T. M.)

Abrudbánya, a corporate town of S.E. Hungary, situated on the slope of the Érczhegység (Ore Mountains), 45 miles S.W. by S. of Klausenburg (*Hung.* Kolozsvár). In Roman times it was the site of a town where resided the *procurator aurarium* of Dacia, and gold ore is still mined in the villages on the neighbouring mountains. The annual produce of these mines is about 34,400 oz. troy of fine gold. Considerable secondary products are silver, iron, copper, lead, and lignite. The ore raised from the mines belonging to the mine-captaincy of Falatna (to which Abrudbánya belongs) in 1899 represented a total value of £972,292. Population (1891), 2992; (1901) 3370; of recent years it has become joined to the village of Abrudfalva with (1901) 4978 inhabitants. It contains good state schools and many handsome buildings.

Abruzzi e Molise, a territorial division of Italy, a mountainous region embracing the middle Apennines and reaching down to the Adriatic on the E. It comprises the provinces of Aquila, Chieti, Teramo, and Campobasso, with an area of 6567 sq. miles, and includes a population of (1881) 1,317,215, (1901) 1,442,365. The first three provinces correspond to the former Neapolitan districts of Abruzzo, and Campobasso to the former Neapolitan province of Molise. The mountains are in great part covered with forests, and the wealth of the people consists principally in cattle, sheep, and pigs. Some wheat, wine, olives, and figs are grown in the valleys. Beyond the rearing of silkworms and silk-spinning, the industries are unimportant. The towns are mostly of small size, the chief of them being Chieti, Teramo, Aquila, Campobasso, and Solmona.

Abt, Franz (1819-1885), German composer, was born 22nd December 1819 at Eilenburg, Saxony, and died at Wiesbaden, 31st March 1885. The best of his popular songs have become part of the recognized folk-music of Germany; his vocal works, solos, part-songs, &c., enjoyed an extraordinary vogue all over Europe in the middle of the 19th century, but in spite of their facile tunefulness have few qualities of lasting beauty. He was Kapellmeister at Bernburg, 1841, at Zürich in the same year, and at Brunswick, 1852-82, when he retired to Wiesbaden.

Abu, a mountain of India, in the Sirohi state of Rajputana, being an isolated spur of the Aravalli range. It is situated in 24° 35' N. lat., and 72° 45' E. long., 16 miles from the Abu road station of the Raj-

putana railway. The height above the sea of the various peaks ranges from about 4000 to 5635 feet. It is the summer residence of the governor-general's agent for Rajputana, and a place of resort for Europeans in the hot weather. The annual mean temperature is about 70°, rising to 90° in April; but the heat is never oppressive. The annual rainfall is about 68 inches. The

hills are laid out with driving-roads and bridle-paths, and there is a beautiful little lake. The chief buildings are a church, club, hospital, and a Lawrence asylum school for the children of British soldiers.

ABYSSINIA.

1. GEOGRAPHY AND STATISTICS.

DURING the last thirty years of the 19th century our knowledge of the physical features, climate, natural history, resources, and social condition of Abyssinia has been greatly advanced by scientific exploration, by hunting and military expeditions, and by the reports of numerous

embassies to the courts of its successive rulers. As fully explained in the historical section (see below), a main result of the political relations, some friendly, some hostile, with Egypt, Italy, and Great Britain, has been the consolidation of the Abyssinian empire under one potentate, Menelek, king of Shoa, by the complete reduction of the ancient kingdoms of Tigré, Lasta, Amhara, and Gojam,

SKETCH MAP OF ABYSSINIA.

followed by the absorption of all the surrounding Ethiopian lands. The area of the unified political system has thus been enlarged, especially in the direction of the south and south-east, while its absolute autonomy has been recognized by various international treaties with Great Britain and Italy. Menelek's dominions now comprise the whole of the Galla and Kaffa highlands, extending from Abyssinia proper southwards nearly to the Samburu (Lake Rudolf) depression, together with Harar and Central Somaliland coterminous with the French, British, and Italian possessions

along the seaboard. In the empire are thus now included, besides the above-mentioned vassal kingdoms, the territories of Ennarea, Guragheh, Walamo, Jimma, Ghera, Guma, Leka, Walega, Kaffa, and all the other petty states which are exclusively occupied by the Hamitic Galla people, and constitute what is commonly called Gallaland or South Ethiopia. The frontiers, mostly conventional lines regardless of mountain ranges, river basins, or other natural features, have not yet been determined towards the N.W., W., and S.; but they roughly coincide to the west towards

the Anglo-Egyptian Sudan, with the meridian of 35° E. between the river Rahad, and 4° N. lat., and on the south with this parallel eastwards to 40° E. Here the line is deflected irregularly south-eastwards to Logh, on the river Juba, and then runs north by east at about 180 miles from the coast along the Italian frontier as far as British Somaliland. Beyond this district the boundary is coterminous eastwards with French Somaliland as defined in 1897, and the Italian colony of Eritrea as far north as 15° N. lat., and westwards to the Atbara, whence the line runs south and west to the point where the river Rahad is intersected by the meridian of 35° E. Within these limits the reconstituted Abyssinian empire has a total area of about 320,000 square miles, with a population approximately estimated at 9,000,000 distributed as under:—

	Area in Sq. Miles.	Population.
Hamran, Beni-Amer, Bilin, Marea, Mensa, Basé (Kunama), and Barea districts between the Plateau and Upper Nubia	30,000	150,000
Abyssinia proper (North Ethiopia): the old kingdoms of Tigré, Lasta, Amhara and Gojam	80,000	2,600,000
Shoa (Menelek's patrimony)	20,000	1,000,000
Harrar and neighbouring districts	10,000	250,000
Ogaden and other parts of Somaliland	100,000	1,000,000
South Ethiopia (Gallaland)	80,000	4,000,000
Total (1901)	320,000	9,000,000

Despite its enlarged domain, Abyssinia still remains an inland state, nowhere reaching the coast, where all its natural outlets—Massawa and Assab on the Red Sea, Jibuti, Zeila, Bulhar, and Berbera on the Gulf of Aden—are held by foreign Powers. Even on the west side it is cut off from direct access to the White Nile, where both banks of the river are included in the Anglo-Egyptian Sudan. No doubt the upper courses of the eastern affluents of the main stream, Sobat, Abai (Blue Nile), Takazzé (Atbara, or Black Nile), flow through Abyssinian territory. But here they have the character of intermittent wadies, nearly dry for a great part of the year, and during the rains raging torrents rushing wildly through deep rocky gorges down to the lowlands, hence at no time navigable, and of little use even for irrigation purposes. Hence their exclusion from marine and fluvial navigable waters has been all the more acutely felt by the native rulers, whose foreign policy continues to be largely directed towards acquiring territory both on the seaboard and along the right bank of the White Nile.

The Ethiopian highlands, of which Abyssinia proper forms the northern, and Gallaland the southern section, occupy most of the space between the lowlands of the White Nile basin and those of the Eritrean rift valley, separating them from the Red Sea and the Indian Ocean. Their long axis is disposed in the direction of the meridian, and the whole region broadens out from near the Red Sea at Massawa southwards to the Lake Rudolf depression. The northern section, lying mainly between 10°-15° N. lat., may be described as a huge mass of Archæan gneiss and schists, forming a rugged plateau at a mean height of from 7000 to 7500 feet above the sea, profoundly weathered by sub-aërial agencies, and flooded in a deep central depression by the waters of Lake Tsana. Above the plateau, which presents its steepest escarpments towards the rift valley, and falls in terraces northwards and westwards down to the plains of Upper Nubia and Sennar, rise several irregular and generally ill-defined mountain ranges, consisting partly of Jurassic limestones and partly of old igneous rocks, great sheets of lava and vast piles of volcanic detritus, which in the western provinces of Gojam and Simen attain altitudes of from 12,000 to 15,000 or even 16,000 feet. But there appear to be nowhere any active cones, and the very craters have for the most part been obliterated. The plateau formation itself is broken and largely obscured by vast yawning chasms and fissures, through which the surface waters escape to the surrounding lowlands. Amid the chaos of Alpine heights and rugged plains which, seen from the higher summits, present the aspect of a storm-tossed sea suddenly

solidified, the best-defined mountain system is the coast range, which is formed by the precipitous eastern escarpments of the plateau, and maintains for a distance of about 600 miles a mean elevation of from 7000 to 8000 feet. It thus rises little above the inland plateau, and travellers penetrating from the coast to the interior find that on surmounting this rocky barrier they have already reached the normal level of the whole region. But the irregular Simen and Gojam groups, the true highlands of North Ethiopia, still rise 6000 or 7000 feet higher, several of their peaks penetrating to the snow-line. Mount Dajan in the Simen range is certainly over 15,000 feet, and was long supposed to be the loftiest summit in Africa north of Kenia. But it now appears to be overtopped by others, such as Abba-yared (15,600 feet), and Buahit (16,000 feet) in the same group. At Ankober (9° N.) the coast range begins to trend round to the south-west, thus assuming the aspect of an inland chain, and gradually increasing in height until it culminates in Mount Metaitih (11,000 feet), and the Entoto range crossed by the Hular Koh Pass (over 12,000 feet) in the kingdom of Shoa. Here the Abyssinian system merges in the South Ethiopian highlands, which are continued at considerable altitudes southwards to the Kaffa territory, and then fall rapidly down to the Lake Rudolf depression. Like the northern section, these less-known Galla uplands appear to form a much broken hilly plateau, presenting its steepest escarpments on the east side towards Somaliland, and falling more gently in a series of broad terraces down to the lowlands of the Nile basin. Although the routes of the explorers in the Galla and Samburu lands have now been connected by the itineraries of Bottego, Donaldson Smith, Wellby, and a few other travellers, no accurate surveys have yet been made, and the heights assigned to the loftier peaks in South Ethiopia (Hamdo, 11,500 feet; Warro, 13,000 feet; Wosho, 16,000 feet) are little more than conjectural. This region, however, is known to be of a far less rugged character than the Abyssinian tableland, and there are few or no traces of the so-called "ambas," that is, isolated blocks or sections caused by erosion and underground agencies, which are such a characteristic feature of the Shoa and Gojam uplands. Some of the intervening rifts and fissures, which somewhat resemble the Mexican barrancas, are of vast extent and depth, but often very narrow. The most remarkable occur along the edge of the central plateau, "where the total fissure exceeds 6500 feet, measured from the summit of the degas (uplands) down to sea-level. Nowhere else can a more convincing proof be observed of the erosive action of running waters. The two walls of certain gorges, rising nearly vertically within a few feet of each other to a height of some hundreds of feet, represent an erosion of hard rock amounting to at least 10,500 million cubic feet" (*Reclus*, x. p. 129).

Most of the Abyssinian uplands have a decided north-westerly tilt, so that nearly all the large rivers find their way in this direction inland to the Nile Valley. Such are the Takazzé in the north, the Abai in the centre, and the Sobat *Rivers and lakes.* in the south, and through these three arteries is discharged about four-fifths of the entire drainage. The rest is carried off by the Khor Baraka, which occasionally reaches the Red Sea below Suakim; the Hawash, which runs out in the saline lacustrine district near the head of Tajura Bay; the Webi-Shebeyli and Juba, which flow through Somaliland to the Indian Ocean; and the Ono, now known to be the main feeder of the closed basin of Lake Rudolf. The Takazzé, which is the true upper course of the Atbara (the *Asaboras* of the ancients, and the *Bahr-el-Aswad* or "Black Nile" of the Arabs), has its source in the Simen uplands, and falls from about 7000 to 2500 feet above sea-level in the tremendous crevasse through which it sweeps round east, north, and west down to the western terraces, where it passes from Abyssinian to Nubian territory. During the rains the Takazzé, *i.e.*, the "Terrible," rises some 18 feet above its normal level, and at this time forms an impassable barrier between the northern and central provinces. In the Hamran district, where it becomes the Bahr-Setit, the Takazzé is joined on its left bank by the Upper Athara, which is formed by the junction of the Angreb, Salaam, Aradeh, Koang, and several other head-streams descending from the Amhara uplands. Below the confluence the united stream retains the name of Athara, and farther down receives on its right bank the intermittent waters of the Mareb or Gash, which rises near Adua in Tigré and is dry for a great part of the year, but, like the Takazzé, is subject to sudden freshets during the rains. From its source to the Nile confluence at Ed-Damer, where it is now crossed by a railway bridge, the main stream has a total length of about 800 miles, and the drainage area exceeds 20,000 square miles within Abyssinian territory. But the discharge is slight except in the wet season, when it nearly equals that of the Blue Nile. In its lower reaches it rises at times to a height of 30 or 40 feet, with a breadth of over 600 yards. The Abai—that is, the upper course of the Blue Nile—has its farthest source near Mount Denguiza, in the Gojam highlands, about 11° N. and 55° E., and first

flows for 70 miles nearly due north to the south side of Lake Tsana (Dembea). This great island-studded basin, which stands some 3000 feet below the normal level of the plateau, has somewhat the aspect of a flooded crater, being of nearly circular form, with a diameter of about 40 miles, an area of over 1200 square miles, and a depth in some parts of 250 feet. Tsana has been identified with the *Coloe Palus* of the ancients, which, although placed some 12° too far south by Ptolemy, was described as a chief reservoir of the Egyptian Nile and the source of the *Astopus*, which was certainly the Blue Nile. At the south-east corner the rim of the crater is, as it were, breached by a deep crevasse through which the Abai escapes, and here develops a great semicircular bend like that of the Takazzé, but in the reverse direction—east, south, and north-west—down to the plains of Sennar. In this section of its course its swirling waters rush over a long series of cataracts and rapids, descending from a height of 6000 feet at the outlet to about 1400 feet at Fazokl, where it crosses the Abyssinian frontier, and flows with a sluggish current through the plains of Sennar to its confluence with the White Nile at Khartum, 1300 feet above sea-level. At Fazokl, where it becomes the *Bahr-el-Azreq* (Blue Nile), it is joined on its left bank by the auriferous Tunat, and higher up by the Yabus, both intermittent affluents from the South Ethiopian uplands. In Sennar it receives on its right bank two important tributaries from the Abyssinian heights, the Dinder, a very long and apparently perennial stream, and the Rahad, waterless in the dry season, copious and richly charged with sediment during the rains from June to September. At this period the discharge of the Blue Nile rises from 6000 to 220,000 cubic feet per second, thus greatly exceeding that of the White Nile itself, which is only about 175,000 cubic feet during the floods above the confluence. The economic importance of the Blue Nile as the great fertiliser of Egypt is elsewhere discussed. (NILE; EGYPT.) On the east side of the Abyssinian plateau the chief fluvial basin is that of the Hawash (Awash, Awasi), which rises on the landward side of the coast range, and, like the other large Ethiopian rivers, describes a great semicircular bend on its seaward coast between the Shoa uplands and Gallaland. After emerging on the Afar (Danakil) lowlands through a broad breach in the eastern escarpments of the plateau, it is joined on its left bank by its chief affluent, the Gernama (Kasam), and then trends round to the north-east in the direction of Tajura Bay. Here the Hawash is a copious stream nearly 200 feet wide and 4 feet deep, even in the dry season, and during the floods rising 50 or 60 feet above low-water mark, thus inundating the plains for many miles along both its banks. Yet it fails at any time to reach the coast, and after a winding course of about 500 miles runs out in the Lake Ausa basin, some 60 or 70 miles from the head of Tajura Bay. This remarkable phenomenon is explained by the position of Ausa in the centre of a saline lacustrine depression, which stands at present several hundred feet below sea-level. Recent surveys give 174 metres for the Assal lakelet near the bay, and several of the other surrounding *baddis* (basins) may even be lower, although the Hawash itself still flows at an elevation of 620 metres below its junction with the river Addifuha, where it begins to descend through a chain of baddis down to Ausa. While most of the other lagoons are highly saline, with thick incrustations of salt round

their margins, Ausa remains fresh throughout the year, owing to the great body of water discharged by the Hawash into this closed basin. Formerly the whole of the Afar and neighbouring Adal (Somali) and Dawari (Galla) territories formed part of the Red Sea, which flooded the now dry rift-valley right up to the foot of the coast range. Another lacustrine region, not however of marine, but perhaps of igneous origin, extends from the Shoa heights southwards to the Samburu depression. In this chain of lovely upland lakes, some fresh, some brackish, some completely closed, others connected by short channels, the chief links in their order from north to south are Zwai, communicating southwards with Hara and Lamina, all in the Arusi Galla territory; then Abai with an outlet to a smaller tarn in the romantic Baroda and Gamo districts, skirted on the west side by grassy slopes and wooded ranges from 6000 to nearly 9000 feet high; lastly, in the Asilli country Count Teleki's Lake Stefanie, the Chuwaha of the natives, completely closed and falling to a level of 3700 feet above the sea. To the same system obviously belongs the neighbouring Lake Rudolf (Gallapa or Buzz), which is larger than all the rest put together, and terminates southwards with an active volcano, thus betraying the igneous origin of these basins and bringing them into line with Gregory's "Great Rift Valley." With the determination of the lower course of the Omo, one of the few remaining problems in African geography has been solved. Its upper course had long been identified with the Fintiré, which rises on the northern slope of the Boré heights about 150 miles south-west of Addis-Abbaba, and, after flowing 38 miles north, bends round east and south to the Zighero district, where it takes the name of Omo. It was then supposed either to trend east to the Juba or west to the Sobat until Bottego, on his last disastrous expedition (1896), found that it discharged into the closed basin of Lake Rudolf. Its lower reaches have since been visited by Cavendish, Donaldson Smith, Austin, Welby, Leontieff, Bulatovich, and others; and the Niamiam, as it is here called, is now known to be a noble perennial waterway, which is joined along its middle course by the Gojeb, Jibíé, Gumi, Kabish, and many other affluents on both its banks, and for some miles above its mouth at the north end of the lake flows in a deep channel varying with the seasons from 50 to 500 feet in width. Throughout its entire length of over 370 miles it has a total fall of about 6000 feet (from 7600 at its source to 1600 at lake-level), and is consequently a very rapid stream, being broken by the Kokoby and other falls, and navigable only for a short distance above its mouth. The Baraka, Shebeyli, Juba, and Sobat, belonging only for short stretches of their upper courses to the Ethiopian region, will be more conveniently described in their principal drainage areas. (NILE; SOMALILAND.)

The vertical disposition of the climatic zones, which is more or less common to all highland regions, and of which Mexico offers a typical example, is somewhat modified on the Ethiopian uplands by the irregular distribution of the rainfall, the varying aspect of the land, and other local conditions. Nevertheless, striking analogies have been observed between the superimposed Mexican and Abyssinian zones, so that it is possible to construct a comparative table of the more salient features, and even of the respective terminologies of each, as under:—

Climatic zones; flora; fauna.

Climatic Zones.		Mean Range of Altitudes.	Mean Range of Temperatures.	Characteristic Flora.
1. (Hot)	{ Mex. Tierra Caliente	0 to 4,000 ft.	77°- 82° F.	Banana, sugar, cocoa-nut, coffee.
	{ Abys. Kwalla	0 to 5,000 ft.	70°-100° F.	Banana, cotton, date, coffee.
2. (Temp.)	{ Mex. Tierra Templada	4000 to 6,000 ft.	62°- 70° F.	Maize, wheat, tobacco, beans.
	{ Abys. Voína-dega	5000 to 8,000 ft.	60°- 80° F.	Wheat, bamboo, terehinth, pulse, citron.
3. (Cold)	{ Mex. Tierra Fria	6000 to 9,000 ft.	58°- 64° F.	Jucca, pine, cedar.
	{ Abys. Degá	9000 to 14,000 ft.	45°- 60° F.	Pine, barley, oats, scrub.

The correspondence is even closer than appears from this table, because the Mexican scheme excludes Alpine heights, which are included in the Abyssinian dega. Allowance has also to be made for the much lower latitude of the Ethiopian region (4°-16° N.) compared with that of Mexico (16°-32° N.), while the mean altitude of the two plateaux is about the same (7000 feet). Besides the above-mentioned plants, many other tropical forms—indigo, tamarinds, ebony, gummiferous acacias, baobabs—flourish in the Kwalla bottom-lands. Nearly all the European cereals, grasses, and shell fruits are indigenous in the Voína-dega, where are also met the orange, peach, apricot, and other fruit trees, besides the vine, *Zegba* (*Podocarpus*), dhurra, tief, kolkwal (*Euphorbia abyssinica*), juniper, and several species of scyamares, some of which grow to a gigantic size in the sheltered gorges of the intermittent mountain torrents. But in the dega, which includes all the more elevated plains, ambas, and upland valleys, little thrives except the hardier cereals, scrubby plants, and rich grasses affording excellent fodder for cattle, goats, and the long-haired native sheep. The South Ethiopian region between the Hawash and White Nile basins has also its three zones, which, as determined

by M. Michel of the Bonchamps Mission (*La Géographie*, July 1900), are:—1. The wide treeless tableland between 6500 and 8500 feet high, covered in places with limestone strata, deeply scored here and there by the running waters. 2. The uplands between the sources of the Hawash and Omo rivers, stretching west to the valley of the Didessa, affluent of the Sobat. Here the ranges, which fall little below 10,000 feet, and are separated by deep valleys, are clothed with low forest, and lower down with scrub which has been partly cleared for cultivation. 3. A low, hilly region from 5000 to 5500 feet high, with scarcely any intervening level ground, but superabundantly watered by streams, flowing to the Sobat, and yielding large quantities of coffee and honey. The hitherto almost unknown region stretching still farther south towards Lakes Rudolf and Stefanie proves to be much more elevated, and also more productive, than had been supposed. Alpine heights—one (Guge) nearly 14,000 feet—are spoken of by Bottego, Donaldson Smith, and other explorers near the lakes, and the waterparting between the Omo and Sobat basins, to which Bulatovich has given the name of the *Tsar Nicholas Range*, is surmounted in its northern section by several peaks over 10,000

feet high. This range is lofty enough to intercept the moisture-charged clouds brought by the trade winds from the Indian Ocean, and thus raise the mean rainfall from 30 inches in Abyssinia proper to 40 or 50 inches on the eastern slopes of the Galla uplands. Here have been discovered clear indications of iron and copper, while gold is known to occur in large quantities in the Tumat valley, where it was for some time profitably mined by Mehemet Ali. Gold, iron, and other metals are also mentioned in the Hammer Koki hills north of Lake Stefanie, and recent exploration fully confirms the reports of the early Italian explorers—Massaja, Antinori, Chiarini, Cecchi, and others—regarding the vast superiority of the Galla lands over the Abyssinian plateau in natural resources of all kinds. Wellby, who traversed the lacustrine region between Shoa and Lake Rudolf in 1898-99, describes the "demon-haunted" Walamo district and the Baroda and Gamo uplands about Lake Abai as "fairly lands," with fertile black and red soils abundantly watered by limpid streams, in parts well timbered or under rich pasturage, and, where cultivated, growing bananas, palms, tobacco, limes, cotton, ginger, raspberries, and *godaris*—"a remarkably good vegetable." Along the banks of the streams "grow big shady trees and a multitude of flowers and undergrowth, alive with birds of bright plumage" (*Geograph. Jour.* September 1900). Whilst extensive woodlands are rarely met with in Abyssinia, except in the Kwalla districts, travellers in the southern uplands speak of the immense forests of conifers, wild olives, and other trees, under the matted moss-grown branches of which they have journeyed for hours together. This home of the coffee-shrub could still supply the world with many other valuable species, such as the *aggieh*, or *korarima*, a fruit much esteemed for its flavour and aroma, and the *kosso*, a beautiful plant with large pendent red flowers, highly prized for its medicinal properties. Besides the elephant, hartebeest, and other large African game, the wild fauna includes the giraffe, rhinoceros, lion, black panther, leopard, hyena, buffalo, gazelles, wild donkeys (striped like a zebra), eagles, vultures, kites, guinea-fowl, partridges, and sand-grouse. Of great economic importance is the civet-cat (*Viverra civetta*), which is domesticated, and yields most of the musk that finds its way to the eastern markets. A more valuable product is coffee, which is indigenous in the Kaffa country, whence it takes its name, and is extensively cultivated throughout the wooded districts of Gallaland. It thrives best on the clearings under the shade of large trees, and is of prime quality; much of the so-called Arabian "mocha" really comes from Ethiopia, and the two sorts are often mixed together for the European markets.

Besides gold, ivory, musk, salt, and coffee, the staples of the export trade, many other commodities, such as corn, flour, beer,

Markets and towns.

korarima, honey, wax, cotton, and indigo, are forwarded to the local markets. Of these the busiest are Basso in the north, Bonga in the extreme south, and Liekà in the centre. Liekà, the largest market in Gallaland, stands on the Bilbò plain near Sopsò, and enjoys direct communication with Gojam, Shoa, and other parts of the empire. Bonga, the commercial centre of Kaffa, is much frequented by traders from all the surrounding provinces, and even by foreign merchants following the routes from Zeila and Berbera on the coast through Harrar and the Arusi Galla territory to South Ethiopia. Apart from these market-places there are few permanent centres of population in Abyssinia. Even these are not towns in the strict sense, but military stations, called *katama*, "camps," by the natives, who have no word for town. Since the fall of the great city of Axum, the so-called "capitals" and royal residences—Adua, Gondar, Magdala, and others—have been little more than overgrown villages, flourishing for a time, and then perhaps suddenly abandoned at the whim of the reigning potentate. Menelek himself has successively shifted his headquarters from Ankober, Litché, Debra-Berham, and Entoto, to Addis Abbaba (Addi-Abbas), the present seat of government both for his kingdom of Shoa and for the empire. This place, which dates only from 1892, stands on the southern slopes of the Entoto range (on which the next preceding capital was situated) on bare, grassy undulations, watered by small streams flowing S.S.E. to the Hawash. The centre of the camp, on which the principal tracks from all directions converge, is the "Gebî" or enclosure of King Menelek, around which straw-thatched native huts, with wattle and mud walls, are scattered in groups over a wide area. The Gebî—which includes the "Elfinage" (Elfig) or two-storeyed dwelling-house, the "aderash" or hall of reception, the "saganet" or clock-bower (used as a hall of justice), and the "guoda" or storehouse—completely covers a small hill overlooking the whole neighbourhood, while around it are the inclosures of the principal nobles. About a mile to the north-east of the palace is the military camp of the king. About thirty miles south of Addis Abbaba can be seen the sacred Mount Zakwalà, while to the south-east lie the fine masses of Mount Yardu, and to the north-west Mount Managasha. On the hills some five miles to the north, 1500 feet above the camp, are the ruins of an old fortress, and the churches of St Raguel and St

Mariam. The frequent change of capital is due in some measure to the destruction of the forest in the neighbourhood, which in time exhausts the supply of fuel and building materials. These are now obtained from the vicinity of Mount Managasha. The palace of Menelek was placed by Captain Germain and Lieutenant Dyé, of the Marchand Mission, by astronomical observations, in $9^{\circ} 1' 4''$ N. lat., $38^{\circ} 42' 50''$ E. long.; but Mr Weld Blundell (*Geogr. Journal*, vol. xv. p. 308, map) places it in $38^{\circ} 56' E.$, which agrees with that assigned in the Italian map by Captain Chaurand (see GLEICHEN, *With the Mission to Menelik*, London, 1898).

In the following list will be found alphabetically arranged all the other important Abyssinian towns regarding which there need be given any information complementary or supplementary to that contained in the 9th edition:—

Addigrat, properly *Add' Igrat*, one of the chief markets in Tigré, east by north of Adua, on a fertile plain about 8000 feet above sea-level, with a permanent population of 1500; to the west is the monastery of *Debra-domo*, one of the most celebrated sanctuaries in Abyssinia. *Adua* (or *Ađowa*), capital of Tigré, and one of the largest markets in Ethiopia, with a population of about 3000. It has played a large part in recent political events, and 13 miles S.E. of here was fought the decisive battle of 1st March 1896, in which the Italians were utterly defeated, and had consequently to renounce their claim to a protectorate over Abyssinia. *Aliu-Amba*, a large market in Shoa, the first station beyond Ankober, on the trade route between that place and the Gulf of Aden; has a permanent population of 4000, chiefly Moslem. *Amba-Mariam*, a fortified station in the province of Beghemeder, midway between Gondar and Debra-Tabor near the north-east side of Lake Tsana, with a population of 3000. Here is the famous shrine and church dedicated to St Mary, whence the name of the place, "Fort St Mary" *Debra-Berham*, "Mountain of Light," a former capital of Shoa, a few miles south of Litché, on the banks of the Beresa, an auriferous head-stream of the Jemma, a tributary of the Blue Nile, with a population of 2500. *Debra-Tabor*, "Mount Tabor," the chief royal residence during the reign of King Johannes, occupies a strong strategic position overlooking the fertile plains east of Lake Tsana, at a height of about 8620 feet above the sea. It has a population of 3000, including the neighbouring station of Samara, headquarters of the Protestant missionaries in the time of King Theodore. *Harrar*, after the withdrawal of the Egyptian garrison, was occupied in 1887 by the Abyssinians with the view of establishing an advanced military and trading station towards the Gulf of Aden. Their claim to the city and surrounding territory has been recognised by international treaties, and here have recently been erected large government buildings in the European style. It is by far the largest town in Abyssinia, with a settled population estimated in 1900 at over 20,000, mostly Mohammedans. Harrar is now a great depot for the distribution of European wares (cottons, silks, cutlery, crockery, beads, &c.) amongst the surrounding Galla and Somali tribes, and throughout the southern provinces of the empire. *Litché* (*Licheh*), till recently the capital of Shoa, and largest market in South Abyssinia, on a terrace watered by a head-stream of the Jemma, a few miles north of Debra-Berham, has a population of 3000. East of this place are the ruins of *Tegulet*, which, after the fall of Axum, was for a time the imperial capital, and gave its name to the present kingdom of Shoa. *Mahdera-Mariam*, "Mary's Rest," for some time a royal residence, and still an important market and great place of pilgrimage in the kingdom of Amhara, a few miles south-west of Debra-Tabor on a head-stream of the Gamera, which flows east to Lake Tsana; its two churches of the "Mother" and the "Son" are amongst the most venerated sanctuaries in the whole of Ethiopia. It has a considerable permanent population estimated at over 4000, Gallas and Amharas, the former mostly Mohammedans. *Sokota*, one of the great central markets, and capital of the province of Wag in Amhara, at the converging point of several main trade routes on the banks of the Bilbis, which flows through the Tsellari to the Takazzé, near the Lasta frontier. The market, which is held three times a week, is numerously attended, especially by dealers in the salt blocks which come from Lake Alalbed, and which are the currency throughout a large part of Ethiopia. In recent years Sokota has suffered much from epidemics, the population falling from about 6000 in 1868 to less than 2000 in 1900.

A railway has been projected to run from the French port of Jibuti, Tajura Bay, through Elba in the Harrar district to Addis Abbaba. The coast section was in progress in 1901, and should it ever be completed the whole way, which seems doubtful, Jibuti must become the chief outlet for the rich and varied produce of Gallaland, much of which at present finds its way by the old caravan route through the Arussi territory to the British ports of Zeila, Bulhar, and Berbera, on the Gulf of Aden. This route, followed from time immemorial by the Arussi and Ittu Gallas, is scarcely known to the outer world, and has not yet been followed by any European traveller. It was known, however, to Cecchi, who was informed by the native traders that beyond Harrar it turns sharply round to the west as far as the neighbourhood of Ankober,

Roads.

where it bifurcates, one branch penetrating into Shoa over the Ittu chain, the other turning south-west and reaching South Ethiopia over a pass in the Arussi range. By this trade route Harrar is reached in a month from the remotest confines of Kaffa, and in two or three weeks from the heart of Gallaland, whereas the northern routes through Abyssinia proper to Massawa and Assab are both much longer and far more difficult. The chief distances are:—Massawa by Saati and Asmara to Adus, capital of Tigré, 104 miles; Adua to Sokota, converging point of several trade routes from the coast and the interior, 110; Sokota to the Italian port of Assab, 240; Sokota to Basso, the great market of Gojam, near the Shoa frontier, 180; Basso to Lieka, the great market of Gallaland, 120; Lieka to Bonga, the great market of Kaffa, 115; Bonga to Harrar over the Arussi Range, 270; Harrar to the coast at Zeila and Jibuti, 192 and 130.

The Ethiopian uplands appear to have been originally peopled by the eastern branch of the Hamitic family, which has occupied

Population. This region from the remotest times, and still constitutes the great bulk of its inhabitants. But their domain was encroached upon probably in the Stone Age, but certainly before the historic period, both by the uncultured negroes of the White Nile and by the cultured Himyaritic Semites from South Arabia. The presence of these elements is still conspicuous, especially in North Ethiopia, where the blends between blacks, Hamites, and Semites are so numerous and widespread that the natives, who call themselves *Itiopianian* ("Ethiopians"), are known to the Arabs as *Habashi* ("mixed"),¹ whence our terms "Abyssinia" and "Abyssinians." Throughout historic times the politically dominant people have been the Semitic Himyarites, who, however, have failed to preserve their racial purity, and have gradually been merged in varying proportions with their Hamitic subjects in the present Abyssinian nationality, whose very dark skin, crisp or curly black hair, and some other physical traits, also betray a distinct strain of black blood. The prevailing colour in the central provinces (Amhara, Gojam) is a deep brown, which shades northwards (Tigré, Lasta) to a light olive, and even fair complexion, and southwards (Shoa, Kobbo, Amuru) to a decided chocolate and almost sooty black. Many are distinctly negroid, with tumid lips, small nose, broad at base, and frizzly or ringlety black hair. But the majority may be described as a mixed Hamito-Semitic people, who belong unquestionably to the Caucasian division of mankind. Several of the indigenous groups, such as the Khamtas of Lasta, the Agaos of Agaomider ("Agaoland"), the Judaizing Falashas, the Khamants of Dembea, still speak rude dialects of the old Hamitic tongue, whose affinities with the Galla, Somal, Afar, Beja, Egyptian, and Berber have now been established. But the official language and that of all the upper classes is Semitic, derived from the ancient Himyaritic, which is the most archaic member of the Semitic linguistic family. It was introduced with the first immigrants from Yemen; and although no longer spoken, the *Geez*, as it is called, is still studied as the liturgical language of the Abyssinian Christians. Its literature consists of numerous translations of Jewish, Greek, and Arabic works, besides a valuable version of the Bible dating apparently from the 4th century, when Christianity was introduced by Frumentius of Alexandria. Its best modern representative is the Tigrifña of Tigré and Lasta, which is much purer but less cultivated than the Amharic dialect, which is current in the central and southern provinces, and much affected by Hamitic elements. All are written in a peculiar syllabic script which, unlike all other Semitic forms, runs from left to right, and is derived from that of the Sabæans and Minæans, still extant in the very old rock inscriptions of South Arabia. The identity has been fully established by the palæographic studies of Bent, Mordtmann, D. H. Müller, and other archæologists. The heterogeneous elements entering into the constitution of the Abyssinians are reflected in their political and social institutions, and especially in their religious beliefs and practices. On a seething mass of African heathendom, already in early times affected by primitive Semitic ideas, was suddenly imposed an undeveloped form of Christianity in the 4th century. While the various ethnical elements have been merged in the composite Abyssinian nation, the primitive and more advanced religious ideas have nowhere been fused in a uniform Christian system. Even the social system is marked by crude notions of justice and absurd "Shamanistic" practices, tempered by a few elevated moral precepts. Foreigners are often surprised at the strange mixture of savagery and lofty notions in a Christian community which, for instance, accounts accidental manslaughter as wilful murder. Dreams, also, are still resorted to for detecting crime. A priest is sent for, and, if his prayers and curses fail, a small boy is drugged, and "whatever person he dreams of is fixed on as the criminal. . . . If he does not dream of the person whom the priest has determined on as the criminal, he is kept under drugs until he does what is required of him"

¹ From Arabic root, *habasha*, to collect, gather, mingle. The derivation has been questioned, but on insufficient grounds.

(Count Gleichen, *With the Mission to Menelik*, 1898). Before Menelek's predecessor, Johannes, the Monophysite Abyssinian Church had only one *abuna* (patriarch), always a Copt, and always consecrated by the patriarch of Alexandria. But Johannes raised the number to three, one each for the then vassal states of Gojam and Shoa, and one for his own kingdom of Tigré, with the title of metropolitan. After his death the bishop of Shoa claimed supreme jurisdiction, and to settle the question of supremacy Menelek created two *abunas*, so that the Abyssinian Church boasts of two primates. (See also ABYSSINIAN CHURCH.)

The Negûs Nagasti is an absolute monarch scarcely controlled in the exercise of unlimited authority even by the *adat* (custom, oral code) respected by most eastern despots. Menelek, whose treatment of his Galla and Somali subjects is well spoken of by Welby and other travellers, governs his own kingdom of Shoa directly, and the other vassal Abyssinian kingdoms indirectly through their several *ras* ("heads," "chiefs"), all supreme within their respective jurisdictions. The outlying southern provinces are administered by governors who are appointed by the Negûs, and who generally seek the aid of the hereditary local chiefs in maintaining order, levying the irregular forces, and collecting tribute. Under the governors are the *déjazmach* and *kanyazmach* (leaders of right and left wings in the army), and under these the *fit-worari* (literally "rhinoceros-horn," or leaders of the advanced guard), who, like the Boer field-cornets, are expected to lead the tribesmen when summoned to fight. Abyssinia can put 300,000 men into the field, 240,000 of them armed with rifles. The emperor keeps court with a certain barbaric pomp, assisted by the *azaj* (master of ceremonies), *alaka* (lord of the treasury), *mustinie* (receivers of tribute), and other dignitaries.

The Abyssinian *Calendar* is as follows:—The Abyssinian year of 365 days (366 in leap year) begins on the 1st of Mâskarram, which corresponds to about our 10th of September. Their months have thirty days each, and are thus named: Mâskarram, Tekemt, Hadâr, Tahsâs, Tarr, Yekâtît, Magawit, Miâziâh, Genbot, Sanni, Hamle, Nas'hi. The remaining five days in the year, termed *Pagmen* or *Quaggimi* (six in leap year—leap day being named *Kadis Yohannis*), are put at the end and treated as holidays. The week-days correspond to ours, but are a week behind: e.g., their Easter Sunday is seven days behind ours. Their reckoning is about seven years eight months behind ours: e.g., our New Year's Day 1901 would be about the 21st Tahsâs of their 1893, and their New Year's Day 1894 would be about our 10th September 1901.

(A. H. K.)

II. HISTORY.

Since the publication in 1875 of the article on Abyssinia, in the 9th edition of the *Encyclopædia Britannica*, the centre of interest in this country has shifted from the northern to the southern provinces; and several sources of information, not then available, have been opened to us. We make therefore no apology for glancing at the earlier history of Shoa, and bringing up to the date of the British Expedition (1867) a sketch of the internal history both of Northern and Southern Abyssinia before proceeding with the more recent history.

For the last 200 years and more Abyssinia has been a conglomeration of provinces and districts, ill defined, loosely connected, and generally at war with each other. Of these the three chief provinces have been Tigré (northern), Amhara including Gondar (central), and Shoa (southern). The seat of government, or rather of overlordship, has usually been Amhara; the ruler of which, calling himself Negûs Nagasti (king of kings, or emperor), has exacted tribute, when he could, from the other provinces. The question of succession as Negûs Nagasti has been largely dependent on the blood in the veins of the claimant. All the Emperors have based their claims on their direct descent from Solomon and the queen of Sheba; but it is needless to say that in many, if not most, cases their success has been due more to the force of their arms than to the purity of their lineage. Some of the rulers of the larger provinces have at times been given, or given themselves, the title of Negûs or king, so that on occasions as many as three, or even more, Negûses have been reigning at the same time; and this must be borne in mind by the student of Abyssinian history in order to avoid confusion of rulers. The whole history of the country is one gloomy record of internecine wars, barbaric deeds and unstable

governments of adventurers usurping thrones, only to be themselves unseated, and of raids, rapine, and pillage. Into this chaos enter from time to time broad rays of sunshine, the efforts of a few enlightened monarchs to evolve order from disorder, and to supply to their people the blessings of peace and civilization. Bearing these matters in mind, we find that during the 18th century the most prominent and beneficent rulers were the Emperor Yesu of Gondar, who died about 1720, Sebastié, Negûs of Shoa (1703-18), Amada Yesu of Shoa, who extended his kingdom and founded Ankóber (1743-74), Tekla Giorgis of Amhara (1770-98?) and Asfa Nassen of Shoa (1774-1807), the latter being especially renowned as a wise and benevolent monarch. The first years of the 19th century were disturbed by fierce campaigns between Guxa, Ras of Gondar, and Wolda Selassié, Ras of Tigré, who were both striving for the crown of Guxa's master, the Emperor Eguale Izeion. Wolda Selassié was eventually the victor, and practically ruled the whole country till his death in 1816 at the age of eighty. Mention must here be made of the first British mission, under Lord Valentia and Mr Henry Salt, which was sent in 1805 to conclude an alliance with Abyssinia, and obtain a port on the Red Sea in case France secured Egypt by dividing up the Turkish empire with Russia. This mission was succeeded by many travellers, missionaries, and merchants of all countries, and the stream of Europeans continued until well into Theodore's reign. To Wolda Selassié succeeded Sabagadis of Agamé, by force of arms, and as Ras of Tigré he introduced various Englishmen, whom he much admired, into the country. He improved the prosperity of his land considerably, but by so doing roused the jealousy of Ras Marié of Amhara—to whom he had refused tribute—and Ubié, son of Hailo Mariam, a governor of Simen. In an ensuing battle (in January 1831), both Sabagadis and Marié were killed, and Ubié retired to watch events from his own province. Marié was shortly succeeded in the Ras-ship of Amhara by Ali, a nephew of Guxa and a Mohammedan. But Ubié, who was aiming at the crown, soon attacked Ras Ali, and after several indecisive campaigns proclaimed himself Negûs of Tigré. To him came many French travellers, chief of whom were Lieut. Lefebvre, charged with political and geographical missions, and Captains Galimier and Ferret, who completed for him a useful triangulation and survey of Tigré and Simen (1840-42).

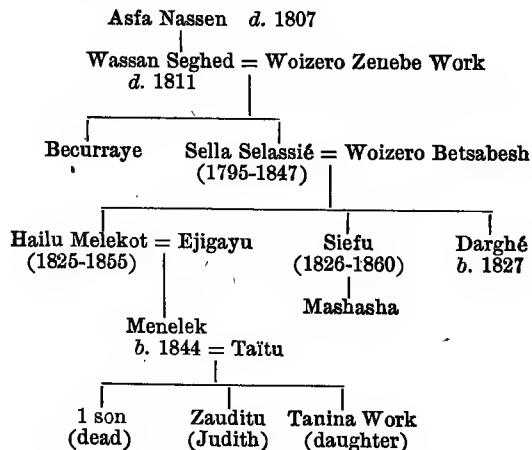

Northern Abyssinia was now divided into two camps, the one, Amhara and Ras Ali, under Protestant British, and the other, Tigré and Ubié, under Roman Catholic French, influence.¹ The latent hostility between the two factions threatened at one time to develop into a religious war, but no serious campaigns took place until Kassa (later Theodore) appeared on the scene. Kassa (b. 1818), son of the chief of Kwara, a western district of Amhara, by his talent and energy rapidly came to the front. In consequence of the arrest of his brother Bilawa by Ras Ali, he raised the standard of revolt against the latter, and, collecting a large force, repeatedly beat the troops that were sent against him by the Ras (1841-47). As his power was increasing, to the detriment of both Ras Ali and Ubié, these two princes combined against him, but were heavily defeated by him at Gorgora (on the southern shore of Lake Tsana) in 1853. Ubié retreated to Tigré, and Ras Ali fled to Begemeder, where he eventually died. Kassa now ruled in Amhara, but his ambition was to attain to supreme power, and he turned his attention to conquering the remaining chief divisions of the country, Gojam,² Tigré, and Shoa, which still

remained unsubdued. Berro, Ras of Gojam, in order to save himself, attempted to combine with Tigré, but his army was intercepted by Kassa and totally destroyed, himself being taken prisoner and executed (May 1854). Shortly afterwards Kassa moved against Tigré, defeated Ubié's forces at Deragié, in Simen (February 1855), took their chief prisoner and proclaimed himself Negûs Nagasti of Ethiopia under the name of Theodore. He now turned his attention to Shoa.

Retracing our steps for a moment in that direction, we find that in 1813 Sahela (or Sella) Selassié, younger son of the preceding Ras Wassan Seghed, had proclaimed himself Negûs or king. His reign was long and beneficent. He restored the towns of Debra Brehan and Angolola, and founded Entoto, the strong stone-built town whose ruins now overlook the modern hut-capital of Addis Abbaba. In the terrible "famine of St Luke" in 1835, Selassié still further won the hearts of his subjects by his wise measures and personal generosity; and by extending his hospitality to Europeans, he brought his country within the closer ken of civilized European Powers. During his reign he received the missions of Major Harris (1841) and M. Rochet d'Héricourt (1843), with both of whom he concluded friendly treaties on behalf of their respective governments. He also wrote to Pope Pius IX., asking that a Roman Catholic bishop should be sent to him. This request was acceded to, and the Pope despatched Monsignor Massaja to Shoa. But before the prelate could reach the country, Selassié was dead (1847), leaving his eldest son, Hailu Meleket, to succeed him. Meleket at once proclaimed himself Negûs, and by sending for Massaja, who had arrived at Gondar, gave rise to the suspicion that he wished to have himself crowned as emperor. By increasing his dominions at the expense of the Gallas, he still further roused the jealousy of the Northerners, and a treaty which he concluded with Ras Ali against Kassa in 1850, determined the latter to crush him at the earliest opportunity.

Thus it was that in 1855 Kassa, under the name of the Emperor Theodore, advanced against Shoa with a large army. Dissensions broke out among the Shoans, and after a desperate and futile attack on Theodore at Debra Brehan, Hailu Meleket died of exhaustion and fever, nominating with his last breath his eleven-year-old son Menelek as successor (November 1855). Darghé, Hailu's brother, took charge of the young prince, but after a hard fight with Angeda, one of Theodore's Rasas, was obliged to capitulate. Menelek was handed over to the Negûs, taken to Gondar and there trained in Theodore's service.

The following shows Menelek's descent since the beginning of the 19th century:—

¹ For names of Europeans, *v.* article in *Ency. Brit.*, 9th edition.

² South of Amhara.

On the retirement of the Northerners, Siefu, another brother of Hailu, proclaimed himself Negûs of Shoa at Ankôber, and beat the local representatives of Theodore's Government. The emperor returned, however, in 1858, and after several repulses, succeeded in entering Ankôber, where he behaved with great cruelty, murdering or mutilating all the inhabitants. Siefu kept up a gallant defence for two more years, but was then killed by Kebret, one of his own chiefs. Thus chaos again reigned supreme in Shoa. In 1865, Menelek, now a Dejzmach of Tigré, took advantage of Theodore's difficulties with the British Government, and escaped to Workitu, queen of the Wollo Galla country. The emperor, who held as hostage a son of Workitu, threatened to kill the boy unless Menelek were given up; but the gallant queen refused, and lost both her son and her throne. The fugitive meanwhile arrived safely in Shoa, and was there acclaimed as Negûs. For the next three years Menelek devoted himself to strengthening and disciplining his army, to legislation, to building towns, such as Litché (near Debra Brehan), Worra Hailu (Wollo Galla country), &c., and to repelling the incursions of the Gallas. On the death of Theodore¹ (13th April 1868), many Shoans, including Ras Darghé, were released, and Menelek began to feel himself strong enough, after a few preliminary minor campaigns, to undertake offensive operations against the northern princes. But these projects were of little avail, for another Kassa, an adventurer of Tigré, had by this time (1872) risen to supreme power in the north. With the help of many rifles and guns, presented to him by the British in return for his help in the campaign, he had beaten Ras Bareya of Tigré, Wagshum Gobassié of Amhara, and Tekla Giorgis of Gondar, and after proclaiming himself Negûs Nagasti under the name of Yohannes or John, was now preparing to march on Shoa. Here, however, Menelek was saved from probable destruction through the action of Egypt. This Power had, by the advice of Munzinger, their Swiss governor of Massawa, seized and occupied in 1872 the northern province of Bogos; and, later on, insisted on occupying Hamasen also, for fear Bogos should be attacked. John, after futile protests, collected an army, and with the assistance of Ras Walad Mikael, hereditary chief of Bogos, advanced against the Egyptian forces, who were under the command of one Arendrup, a Dane. Meeting near the Mareb, the Egyptians were beaten in detail, and almost annihilated at Gundet (13th November 1875). An avenging expedition was prepared in the spring of the following year, and, numbering 14,000 men under Ratib Pasha, Loring (American), and Prince Hassan, advanced to Gura and fortified a position in the neighbourhood. Although reinforced by Walad Mikael, who had now quarrelled with John, the Egyptians were a second time (25th March 1876) heavily beaten by the Abyssinians, and retired, losing an enormous quantity of both men and rifles. Colonel Gordon, governor-general of the Sudan, was now ordered to go and make peace with John, but the king had moved south with his army, intending to punish Menelek for having raided Gondar whilst he, John, was engaged with the Egyptians.

Menelek's kingdom was meanwhile torn in twain by serious dissensions which had been instigated by his concubine Bafana. This lady, to whom he was much attached, had been endeavouring to secure the succession of one of her own sons to the throne of Shoa, and had almost succeeded in getting rid of Mashasha, son of Siefu and cousin of Menelek, who was the apparent heir. On the approach of John, the Shoans united for a time

against their common enemy. But after a few skirmishes they melted away, and Menelek was obliged to submit and do obeisance to John. The latter behaved with much generosity, but at the same time imposed terms which effectually deprived Shoa of her independence (March 1878). In 1879 Gordon was sent on a fresh mission to John on behalf of Egypt; but he was treated with scant courtesy, and was obliged to leave the country without achieving anything permanent.

The Italians now come on the scene. Assab, a port near the southern entrance of the Red Sea, had been bought from the local Sultan in 1869 by an Italian company, which, after acquiring more land in 1879 and 1880, was bought out by the Italian Government in 1882. In this year Count Antonelli was despatched to Shoa in order to improve the prospects of the colony by treaties with Menelek and the Sultan of Aussa. Several missions followed upon this one, with more or less successful results; but both John and Menelek became uneasy when Beilul was occupied by the Italians in January 1885, and Massawa taken over by them from Egypt in the following month. This latter act was greatly resented by the Abyssinians, for by a treaty concluded with a British and Egyptian mission under Admiral Hewett and Mason Pasha² in the previous year, free transit of goods was to be allowed through this port. Matters came to a head in January 1887, when the Abyssinians, in consequence of a refusal from General Gene to withdraw his troops from Waa and Tula, surrounded and massacred 400 Italian troops at Dogali. Reinforcements were sent from Italy, whilst in the autumn the British Government stepped in and tried to mediate by means of a mission under Mr (afterwards Sir Gerald) Portal. His mission, however, proved abortive, and after many difficulties and dangers he returned to Egypt at the end of the year. In April 1888, the Italian forces, numbering over 20,000 men, came into touch with the Abyssinian army; but negotiations took the place of fighting, with the result that both forces retired, the Italians only leaving some 5000 troops in Eritrea, as their colony was now called. Meanwhile John had not been idle with regard to the Dervishes. Although he had set his troops in motion too late to relieve Kassala, Ras Alula, his chief general, had succeeded in inflicting a handsome defeat on Osman Digna at Amideb in July 1887. A large force of Dervishes had, however, entered and sacked Gondar in April 1887, and to avenge this John took the field in force against the enemy, who were still harassing the north-west of his territory. A great battle ensued at Gallabat, in which the Dervishes, under Zeki Tumul, were at first beaten. But a stray bullet pierced John's heart, and his men fled, leaving camp and stores, besides the body of their emperor, in the hands of the enemy (9th March 1889).

Immediately the news reached Menelek he proclaimed himself emperor, and received the submission of Gondar, Gojam, and several other provinces. In common with other northern princes, Mangasha, reputed son and heir of King John, and Ras Alula, refused to acknowledge the sovereignty of Menelek, but on the latter marching against them in the following January with a large army, they submitted. As it happened, Count Antonelli was with Menelek when he claimed the throne, and promptly concluded with him on behalf of Italy a friendly treaty, to be known hereafter as the famous Ucciali treaty. In consequence of this the Italians occupied Asmara, made friends with Mangasha, and received Ras Makunnen,³

² The main object of this mission was to seek John's assistance in evacuating the Egyptian garrisons in the Sudan, which were threatened by the Dervishes.

³ Ras of Harrar, which province had been conquered and occupied by Menelek in January 1887.

¹ For details of Theodore's life and the British expedition, *v. Ency. Brit.*, 9th edition.

Menelek's nephew, as his plenipotentiary in Italy. Thus it seemed as though hostilities between the two countries had come to a definite end, and that peace was assured in the land. For the next three years the land was fairly quiet, the chief political events being the convention (6th February 1891) between Italy and Abyssinia, protocols between Italy and Great Britain (24th March and 15th April 1891), and a proclamation by Menelek (10th April 1891), all on the subject of boundaries. As, however, the Italians became more and more friendly with Mangasha and Tigré the apprehensions of Menelek increased, till at last, in February 1893, he wrote denouncing the Ucciali treaty, which differed in the Italian and Amharic versions. According to the former, the Negûs was bound to make use of Italy as a channel for communicating with other Powers, whereas the Amharic version left it optional. Meanwhile the Dervishes were threatening Eritrea. A fine action by Colonel Arinondi gained Agordat for Italy (21st December 1893), and a brilliant march by Colonel Baratieri resulted in the acquisition of Kassala (17th July 1894). But on his return Baratieri found that Mangasha was intriguing with the Dervishes, and had actually crossed the frontier with a large army. At Koatit and Senafe (13th to 15th January 1895) Mangasha was met and heavily defeated by Baratieri, who occupied Adigrat in March. But as the year wore on the Italian commander pushed his forces unsupported too far to the south. Menelek was advancing with a large army in national support of Mangasha, and the subsequent reverses at Amba Alagi (7th December 1895) and Makalle (23rd January 1896) forced the Italians to fall back.

Reinforcements of many thousands were meanwhile arriving at Massawa, and in February Baratieri took the field at the head of over 13,000 men. Menelek's army, amounting to about 90,000, had during this time advanced, and was occupying a strong position at Abba Garima, near Adua. Here Baratieri attacked him on the 1st March, but the difficulties of the country were great, and one of the four Italian brigades had pushed too far forward. This brigade was attacked by overwhelming numbers, and on the remaining brigades advancing in support, they were successively cut to pieces by the encircling masses of the enemy. The Italians lost nearly 4000 killed and wounded and 2000 prisoners, whilst the Abyssinians owned to a loss of over 3000. General Baldissera advanced with a large body of reinforcements to avenge this defeat, but the Abyssinians, desperately short of supplies, had already retired, and beyond the peaceful relief of Adigrat no further operations took place. It may here be remarked that the white prisoners taken by Menelek were exceedingly well treated by him, and that he behaved throughout, as he has ever since, with the greatest humanity and dignity. A peace was signed at Addis Abbaba in the following October, and negotiations on the question of frontiers were commenced, which were only brought to a conclusion in the autumn of 1900.

This war, so disastrous to Italy, attracted the attention of all Europe to Abyssinia and its monarch, and numer-

ous missions, two Russian, three French, and one British, were despatched to the country and hospitably received by Menelek. The British one, under Mr (now Sir) Rennell Rodd, concluded a friendly treaty with Abyssinia (15th May 1897), but did not, except in the direction of Somaliland, touch on frontier questions, which still form a subject of discussion. During the same year a small French expedition under Messrs Clochette and De Bonchamps endeavoured to reach the Nile, but, after surmounting many difficulties, stuck in the marshes of the Upper Sobat and was obliged to return. Another expedition of Abyssinians, under Dejaz Tasamma, and accompanied by three Europeans—a Frenchman, a Swiss, and a Russian—started early in 1898, and reached the Nile at the Sobat mouth in June, a few days only before Major Marchand and his gallant companions arrived on the scene. But no contact was made, and the expedition returned to Abyssinia. In the same year (1898) Menelek proceeded northwards with a large army, for the purpose of chastising Mangasha, who was again rebelling against his authority. After some trifling fighting Mangasha submitted, and Ras Makonnen despatched a force to subdue Beni Shangul, the chief of which gold country, Wad Tur el Guri, was showing signs of disaffection. This effected, the Abyssinians almost came into contact with the Egyptian troops sent up the Blue Nile (after the occupation of Khartoum) to Famaka and towards Gallabat. But as both sides were anxious to avoid a collision, no hostile results ensued, and matters remain on a friendly footing between the nations. Negotiations and surveys on the subject of frontiers were in progress, and were likely to be brought to a successful conclusion in 1901.

Since 1897 British influence in Abyssinia, owing largely, no doubt, to the conquest of the Sudan, the destruction of the Dervish power, and the result of the Fashoda incident, has been sensibly on the increase. But it remains to be seen whether any European influence will be of much avail after the demise of the present enlightened emperor, or whether Abyssinia will relapse into the state of anarchy and desolation which has characterized so much of her history.

Abyssinian Church.—As the chronicle of Axum relates, Christianity was adopted in Abyssinia in the 4th century. About 330 A. D. Frumentius was made first Bishop of Ethiopia by Athanasius, patriarch of Alexandria. Cedrenus and Nicephorus err in dating Abyssinian Christianity from Justinian c. 542. From Frumentius to the present day, with one break, the Metropolitan has always been appointed from Egypt, and, oddly enough, he is always a foreigner. Little is known of

church history down to the period of Jesuit rule, which broke the connexion with Egypt from about 1500 to 1633. But the Abyssinians rejected the Council of Chalcedon, and still remain monophysites. Union with the Coptic Church (*q.v.*) continued after the Arab conquest in Egypt. Alû Sâlih records (12th century) that the patriarch used always to send letters twice a-year to the kings of Abyssinia and Nubia, till Al Hâkim stopped the practice. Cyril, 67th patriarch, sent Severus as bishop, with

orders to put down polygamy, and to enforce observance of canonical consecration for all churches. These examples show the close relations of the two churches in the Middle Ages. But late in the 15th century, the church was taken captive by a Portuguese mission. In 1439 an Abyssinian embassy to Rome had resulted in the despatch of a mission under Alvarez. Later, Ignatius Loyola wished to essay the task of conversion, but was forbidden. Instead, the Pope sent out Barret as patriarch of the East Indies, with Oviedo as bishop; and from Goa envoys went to Abyssinia, followed by Oviedo himself, to secure the king's adherence to Rome. After repeated failures some measure of success was achieved, but not till 1604 did the king make formal submission to the Pope. Then the people rebelled and the king was slain. Fresh Jesuit victories were followed sooner or later by fresh revolt, and Roman rule hardly triumphed, when once for all it was overthrown. In 1633 the Jesuits were expelled and allegiance to Alexandria resumed.

There are many early rock-cut churches in Abyssinia, closely resembling the Coptic. After these, two main types of architecture are found—one basilican, the other native. The cathedral at Axum is basilican, though the early basilicas are nearly all in ruins—*e.g.*, that at Adulis and that of Martula Mariam in Gojan, rebuilt in the 16th century, on the ancient foundations. These examples show the influence of those architects who, in the 6th century, built the splendid basilicas at Samâ and elsewhere in Arabia. Of native churches there are two forms—one square or oblong, found in Tigré; the other circular, found in Amhara and Shoa. In both, the sanctuary is square and stands clear in the centre. An outer court, circular or rectangular, surrounds the body of the church. The square type may be due to basilican influence, the circular is a mere adaptation of the native hut: in both, the arrangements are obviously based on Jewish tradition. Church and outer court are usually thatched, with wattled or mud-built walls adorned with rude frescoes. The altar is a board on four wooden pillars having upon it a small slab (*tabût*) of alabaster, marble, or shiftim wood, which forms its essential part. At Martula Mariam, the wooden altar overlaid with gold had two slabs of solid gold, one 500, the other 800 ounces in weight. The ark kept at Axum is described as 2 feet high, covered with gold and gems. The liturgy was celebrated on it in the king's palace at Christmas, Epiphany, Easter, and Feast of the Cross.

Generally the Abyssinians agree with the Copts in ritual and practice. The LXX. version was translated into Geez, the literary language, which is used for all services, though hardly understood. Saints and angels are highly revered, if not adored, but graven images are forbidden. Fasts are long and rigid. Confession and absolution, strictly enforced, give great power to the priesthood. The clergy must marry, but once only. Pilgrimage to Jerusalem is a religious duty and covers many sins. (See also under **ABYSSINIA**.)

Academy, French.—The history of the French Academy has continued its tranquil course since 1875, marked perhaps in later years by a greater desire to re-

spond to the purely literary dictates of its composite conscience. Its elections, under the Republic, have been social functions of a highly fashionable character. One alteration in its methods has to be chronicled: in 1869 it became the custom to discuss the claims of the candidates at a preliminary meeting of the members. In 1880, on the instance of the philosopher Caro, supported by A. Dumas fils, and by the aged Désiré Nisard, it was decided to abandon this method, which led to great inconvenience in practice. A point upon which much stress is often laid, and regarding which the most inaccurate statements are put forth, is the degree in which, since its foundation, the French Academy has or has not represented the best literary life of France. On this subject it may be well to supply some supplementary information. It appears from an examination of the lists of members that a surprising number of authors of the highest excellence have, from one cause or another, escaped the honour of academic "immortality." When the Academy was founded in 1634, the moment was not a very brilliant one in French letters. Among the forty original members we find only ten who are remembered in literary history; of these there are four who may reasonably be considered famous still—Balzac, Chapelain, Racan, and Voiture. In that generation Scarron was never one of the forty, nor do the names of Descartes, Malebranche, or Pascal occur; it must not be supposed that any lack of honour was intended to these philosophers, but the French Academy had not come to consider its doors open to this class of writers. The duke of Rochefoucauld declined the honour from a proud modesty, and Rotrou died too soon to be elected. The one astounding omission of the 17th century, however, is the name of Molière, who was excluded by his profession as an actor. On the other hand, the French Academy was never more thoroughly representative of letters than when Boileau, Corneille, La Fontaine, Racine, and Quinault were all members of its body. Of the great theologians of that and the subsequent age, the Academy contained Bossuet, Fléchier, Fénelon, and Massillon, but not Bourdaloue. La Bruyère and Fontenelle were among the forty, but not Saint-Simon, whose claims as a man of letters were unknown to his contemporaries. Early in the 18th century almost every literary personage of eminence found his place naturally in the Academy. The only exceptions of importance were Vauvenargues, who died too early for the honour, and two men of genius of dubious social position, Lesage and the Abbé Prévost d'Exiles. As the Revolution approached, the *personnel* of the Academy became greatly disturbed. Montesquieu and Voltaire belonged to it, but not Rousseau or Beaumarchais. Of the Encyclopædist, the French Academy opened its doors to D'Alembert, Condorcet, Volney, Marmontel, and La Harpe, but not to Diderot, Rollin, Condillac, Helvetius, or the Baron d'Holbach. It is to be supposed that the claims of Turgot and of Quesnay did not appear to the Academy sufficiently literary, since neither was elected. In the transitional period, when the social life of Paris was distracted and the French Academy provisionally closed, neither André Chénier nor Benjamin Constant, nor Joseph de Maistre became enrolled among its members. In the early years of the 19th century considerations of various kinds excluded from the ranks of the forty the dissimilar names of Lamennais, Prudhon, Comte, and Béranger. Critics of the French Academy are fond of pointing out that neither Stendhal, nor Balzac, nor Théophile Gautier, nor Flaubert, penetrated into the Mazarine Palace. It is not so often remembered that writers so academic as Thierry, and Michelet, and Quinet, suffered the same exclusion. In later times neither Alphonse Daudet nor Edmond de

Goncourt, Guy de Maupassant nor Ferdinand Fabre, has been among the forty immortals. The non-election, after a long life of distinction, of the scholar Fustel de Coulanges, is less easy to account for. Verlaine, although a man of great genius, was an example of the kind of person no academy can ever be expected to recognize. Of the degree in which the French Academy represented the highest literary ability during the last quarter of the 19th century, an examination of the following facts will offer evidence. Of the forty members who composed its body at the close of 1875 only three were still alive in the summer of 1901. These were M. Ernest Legouvé, who was elected so long ago as 1855; M. Emile Ollivier, elected on the 7th of April 1870, but, in consequence of the intractability of his political opinions, never formally received; and M. Mézières, elected in 1874. The first death to occur in the Academy was that of Patin; he was succeeded in June 1876 by the distinguished Latinist, M. Gaston Boissier. To succeed the poet Autran, M. Victorien Sardou was elected on the 7th of June 1877; his success was hotly contested by the duke of Audiffret-Pasquier, and one vote transferred would have annulled the election. In 1878, at the death of Thiers, his seat was taken by Henri Martin, that of Bernard by Ernest Renan, and that of Loménie by Taine. In December of that year, at the death of Dupanloup, no opposition was offered to the duke of Audiffret-Pasquier, although he was in the unique position of having never published anything of a literary character. For two years there was no change in the composition of the French Academy, but in 1880 several new names were added; Maxime du Camp succeeded to Saint-René Taillandier, Labiche to Sacy, and M. Rousse to Jules Favre. In 1881 the absence of the younger poets from the Academy, which had been much commented on, was reformed by the election of M. Sully-Prudhomme in the place of Duvergier de Hauranne. In the same year Pasteur followed Littré, and Cherbuliez Dufaure. At the death of the poet Barbier, Perraud, bishop of Autun, was unanimously elected in 1882; later on in the same year Pailleron replaced Charles Blanc and Mazade Champagny. At the death of Sandeau, the popular writer, Edmond About, was elected to take his place, but died (January 1885) too soon to be received. The elections in the latter part of 1884 were more numerous than they had been, in a similar period, within the memory of man. M. Coppée had been admitted in February to take the place of the poet Laprade. The winter elections of 1884 included Lesseps in the room of Martin, Duruy in that of Mignet, Bertrand in that of J. B. Dumas, and M. Halévy in that of the count of Haussonville. After this extraordinary influx the Academy was for some time at rest, but in 1886 four *fauteuils* had to be filled; that of About was taken by Léon Say; that of Victor Hugo (at his expressed wish) by Leconte de Lisle; that of the duke of Noailles by Edouard Hervé; and that of the count of Falloux by M. Gréard. The philosopher Caro having died (July 1887), he was replaced by the historian, Count Othenin de Haussonville in 1888. The most aged member of the Academy, Viel-Castel, who had been born in 1800, died 4th Oct. 1887, and was succeeded by Admiral Jurien de la Gravière; Labiche (d. Jan. 1888) was succeeded by Meilhac; and Désiré Nisard (d. 25th March 1888) by the Viscount Melchior de Vogüé, all these in 1888. Angier, the playwright, dying on 25th October 1889, his *fauteuil* was filled by M. de Freycinet, after a prolonged struggle (11th December 1890). Octave Feuillet dying (28th December 1890), three novelists contended for his seat—Emile Zola, Ferdinand Fabre, and Pierre Loti. At the first voting M. Zola stood at the top of the poll, at the sixth scrutiny

Pierre Loti was declared elected. M. Ernest Lavisse, the historian, succeeded Admiral de la Gravière in 1892. In 1893, after the death of Xavier Marmier, Viscount Henri de Bornier, the poet, who had been a constant applicant for several years, was at length elected by a large majority. M. Thureau-Dangin on the same day succeeded Rousset; in March Challemeil-Lacour followed Renan (died October 1892); and in June M. Brunetière the critic, the journalist John Lemoinne. It proved impossible for the Academy to come to any understanding about the *fauteuil* of Taine (who died March 1893), and the election was therefore postponed. In the meantime Mazade died, and was replaced by the poet Heredia, in February 1894. Finally, after what seemed an endless struggle, the historian, M. Albert Sorel, secured in May 1894 the vacant *fauteuil* of Taine; and M. Paul Bourget was elected on the same day to succeed Du Camp. Later elections to the French Academy have been as follows: in 1894, M. Henry Houssaye; in 1895, M. Jules Lemaitre; in 1896, MM. Anatole France, the Marquis Costa de Beauregard, Gaston Paris, André Theuriet, and Albert Vandal; in 1897, the count de Mun and M. Gabriel Hanotaux; in 1898, the sculptor M. Eugène Guillaume, and the farce-writer M. Henri Lavendan; in 1899, the politician M. Paul Deschanel; in 1900, the novelist M. Paul Hervieu and the critic M. Emile Faguet, both elected on the 15th of February, and on the 28th of June, M. Berthelot; in 1901, the Marquis de Vogüé, the archæologist, and M. Edmond Rostand, the poet and dramatist, both on 30th May.

(E. G.)

Academy, Royal.—The Royal Academy of Arts in London, to give it the original title in full, was founded in 1768, “for the purpose of cultivating and improving the arts of painting, sculpture, and architecture.” Many attempts had previously been made in England to form a society which should have for its object the advancement of the fine arts. Sir James Thornhill, his son-in-law Hogarth, the Dilettanti Society, made efforts in this direction, but their schemes were wrecked by want of means. Accident solved the problem. The crowds that attended an exhibition of pictures held in 1758 at the Foundling Hospital for the benefit of that charity, suggested a way of making money hitherto unsuspected. Two societies were quickly formed, one calling itself the “Society of Artists,” and the other the “Free Society of Artists.” The latter ceased to exist in 1774. The former flourished, and in 1765 was granted a royal charter under the title of the “Incorporated Society of Artists of Great Britain.” But though prosperous it was not united. A number of the members, including the most eminent artists of the day, resigned in 1768, and headed by William Chambers, the architect, and Benjamin West, presented on 28th November in that year to George III., who had already shown his interest in the fine arts, a memorial soliciting his “gracious assistance, patronage and protection,” in “establishing a society for promoting the arts of design.” The memorialists stated that the two principal objects they had in view were the establishing of “a well-regulated school or academy of design for the use of students in the arts, and an annual exhibition open to all artists of distinguished merit; the profit arising from the last of these institutions” would, they thought, “fully answer all the expenses of the first,” and, indeed, leave something over to be distributed “in useful charities.” The king expressed his agreement with the proposal, but asked for further particulars. These were furnished to him on 7th December and approved, and on 10th December they were submitted in form, and the document embodying them received his signature, with

the words "I approve of this plan; let it be put into execution." This document, known as the "Instrument," defined under twenty-seven heads the constitution and government of the Royal Academy, and contained the names of the thirty-six original members nominated by the king. Changes and modifications in the laws and regulations laid down in it have of course been made, but none of them without the sanction of the sovereign, and the "Instrument" remains to this day in all essential particulars the Magna Charta of the society. Four days after the signing of this document—on 14th December—twenty-eight of the first nominated members met and drew up the Form of Obligation which is still signed by every academician on receiving his diploma, and also elected a president, keeper, secretary, council, and visitors in the schools; the professors being chosen at a further meeting held on the 17th. No time was lost in establishing the schools, and on 2nd January 1769 they were opened at some rooms in Pall Mall, a little eastward of the site now occupied by the Junior United Service Club, the president, Sir Joshua Reynolds, delivering on that occasion the first of his famous "discourses." The opening of the first exhibition at the same place followed on 26th April.

The king when founding the Academy undertook to supply out of his own privy purse any deficiencies between the receipts derived from the exhibitions and the expenditure incurred on the schools, charitable donations for artists, &c. For twelve years he was called upon to do so, and contributed in all something over £5000, but in 1781 there was a surplus, and no further call has ever been made on the royal purse. George III. also gave the Academy rooms in what was then his own palace of Somerset House, and the schools and offices were removed there in 1771, but the exhibition continued to be held in Pall Mall, till the completion in 1780 of the new Somerset House, when the Academy took possession of the apartments in it which the king, on giving up the palace for Government offices, had expressly stipulated should be provided. Here it remained till 1837, when the Government, requiring the use of these rooms, offered in exchange a portion of the National Gallery, then just erected in Trafalgar Square. The offer, which contained no conditions, was accepted. But it was not long before the necessity for a further removal became imminent. Already in 1850 notice was given by the Government that the rooms occupied by the Academy would be required for the purposes of the National Gallery, and that they proposed to give the Academy £40,000 to provide themselves with a building elsewhere. The matter slumbered, however, till 1858, when the question was raised in the House of Commons as to whether it would not be justifiable to turn the Academy out of the National Gallery without making any provision for it elsewhere. Much discussion followed, and a royal commission was appointed in 1863 "to inquire into the present position of the Royal Academy in relation to the fine arts, and into the circumstances and conditions under which it occupies a portion of the National Gallery, &c." In their report, which contained a large number of proposals and suggestions, some of them since carried out, the commissioners stated that they had "come to the clear conclusion that the Royal Academy have no legal, but that they have a moral claim to apartments at the public expense." Negotiations had been already going on between the Government and the Academy for the appropriation to the latter of a portion of the site occupied by the recently purchased Burlington House, on which the Academy offered to erect suitable buildings at its own expense. The negotiations were renewed in 1866, and in March in

the following year a lease of old Burlington House, and of a portion of the garden behind it, was granted to the Academy for 999 years at a peppercorn rent, subject to the condition that "the premises shall be at all times exclusively devoted to the purpose of the cultivation of the fine arts." The Academy immediately proceeded to erect, on the garden portion of the site thus acquired, exhibition galleries and schools, which were opened in 1869, further additions being made in 1884. An upper storey was also added to old Burlington House, in which to place the diploma works, the Gibson statuaries, and other works of art. Altogether the Academy, out of its accumulated savings, has spent on these buildings more than £160,000. They are its own property, and are maintained entirely at its expense.

The government of the Academy was by the "Instrument" vested in "a president and eight other persons, who shall form a council." Four of these were to retire every year, and the seats were to go by rotation to every academician. The number was increased in 1870 to twelve, and reduced to ten in 1875. The rules as to retirement and rotation are still in force. Newly-elected academicians begin their two years' service as soon as they have received their diploma. The council has, to quote the "Instrument," "the entire direction and management of the business" of the Academy in all its branches; and also the framing of new laws and regulations, but the latter, before coming into force, must be sanctioned by the general assembly and approved by the Sovereign. The general assembly consists of the whole body of academicians, and meets on certain fixed dates and at such other times as the business may require; also at the request to the president of any five members. The principal executive officers of the Academy are the president, the keeper, the treasurer, the librarian, and the secretary, all now elected by the general assembly, subject to the approval of the Sovereign. The president is elected annually on the foundation day, 10th December, but the appointment is virtually for life. No change has ever been made in the conditions attached to this office, with the exception of its being now a salaried instead of an unsalaried post. The treasurership and librarianship, both offices originally held not by election but by direct appointment from the Sovereign, are now elective, the holders being subject to re-election every five years, and the keepership is also held upon the same terms; while the secretarieship, which up to 1873 had always been filled like the other offices by an academician, has since then been held by a layman. Other officers elected by the general assembly are the auditors (three academicians, one of whom retires every year), the visitors in the schools (academicians and associates); and the professors of painting, sculpture, and architecture—who must be members—and of anatomy and chemistry. There are also a registrar, and curators and teachers in the schools, who are appointed by the council.

The thirty-six original academicians were named by George III. Their successors have been elected, up to 1867, by academicians only—since that date by academicians and associates together. The original number was fixed in the "Instrument" at forty, and has so remained. Each academician on his election has to present an approved specimen of his work—called his diploma work—before his diploma is submitted to the Sovereign for signature. On receiving his diploma he signs the Roll of Institution as an academician, and takes his seat in the general assembly. The class of associates, out of whom alone the academicians can be elected, was founded in 1769—they were "to be elected from amongst the exhibitors, and be entitled to every advantage enjoyed by

the royal academicians, excepting that of having a voice in the deliberations or any share in the government of the Academy." Those exhibitors who wished to become candidates had to give in their names at the close of the exhibition. This condition no longer exists, candidates having since 1867 merely to be proposed and seconded by members of the Academy. On election, they attend at a council meeting to sign the Roll of Institution as an associate, and receive a diploma signed by the president and secretary. In 1867 also associates were admitted to vote at all elections of members; in 1868 they were made eligible to serve as visitors in the schools; and in 1886 to become candidates for the professorships of painting, sculpture, and architecture. At first the number of associates was limited to twenty; in 1866 the number was made indefinite with a minimum of twenty, and in 1876 the minimum was raised to thirty. Vacancies in the lists of academicians and associates caused by death or resignation can be filled up at any time within five weeks of the event, except in the months of August, September, and October, but a vacancy in the associate list caused by election only dates from the day on which the new academician receives his diploma. The mode of election is the same in both cases, first by marked lists and afterwards by ballot. All who at the first marking have four or more votes are marked for again, and the two highest then go to the ballot. Engravers have always constituted a separate class, and up to 1855 they were admitted to the associateship only, the number, six, being in addition to the other associates; now the maximum is four, of whom not more than two may be academicians. A class of honorary retired academicians was established in 1862, and of honorary retired associates in 1884. The first honorary foreign academicians were elected in 1869. The honorary members consist of a chaplain, an antiquary, a secretary for foreign correspondence, and professors of ancient history and ancient literature. These posts, which date from the foundation of the Academy, have always been held by distinguished men.

Schools.—One of the most important functions of the Royal Academy, and one which for nearly a century it discharged alone, was the instruction of students in art. The first act, as has been shown, of the newly-founded Academy was to establish schools—"an Antique Academy" and a "School for the Living Model" for painters, sculptors, and architects. In the first year, 1769, no fewer than seventy-seven students entered. A school of painting was added in 1815, and special schools of sculpture and architecture in 1871. It would occupy too much space to follow the various changes that have been made in the schools since their establishment. In one important respect, however, they remain the same, viz., in the instruction being gratuitous—no fees have ever been charged. Up to the removal of the Academy to its present quarters the schools could not be kept permanently open, as the rooms occupied by them were wanted for the exhibition. They are now open all the year round with the exception of a fortnight at Christmas, and the months of August and September. They consist of an antique school, upper and lower schools of painting, a school of drawing from the life, a school of modelling from the life, and an architectural school. Admission is gained by submitting certain specimens of drawing or modelling, and the successful candidates, called probationers, have then to undergo a further test in the schools, on passing which they are admitted as students for three years. At the end of that time they are again examined, and if qualified admitted for a further term of two years. These examinations are held twice a year, in January and July. Female students were first admitted in 1860. There are many scholarships, money prizes, and medals to be gained by the various classes of students during the time of studentship, including travelling studentships of the value of £200 for one year, gold and silver medals, and prizes varying from £50 to £10. There are permanent curators and teachers in all the schools, but the principal teaching is done by the visitors, academicians, and associates, elected to serve in each school. The average cost of maintaining these schools, including salaries, fees, cost of models, prizes, books, maintenance of building, &c., has been for the last thirty years from £5000 to £6000 a year. This sum does not include the cost of certain scholar-

ships and prizes derived from moneys given or bequeathed for this purpose, such as the Landseer scholarships, the Creswick prize, the Armitage prizes, and the Turner scholarship and gold medal.

Charities.—Another of the principal objects to which the profits of the Royal Academy have been devoted has been the relief of distressed artists and their families. From the commencement of the institution a fund was set apart for this purpose, and subsequently a further sum was allotted to provide pensions for necessitous members of the Academy and their widows. Both these funds were afterwards merged in the general fund, and various changes have from time to time been made in the conditions under which pensions and donations have been granted and in their amount. At the present time pensions not exceeding a certain fixed amount may be given to academicians and associates, sixty years of age, who have retired and whose circumstances show them to be in need, provided the sum given does not make their total annual income exceed a certain limit, and the same amounts can be given to their widows subject to the same conditions. No pensions are granted without very strict inquiry into the circumstances of the applicant, who is obliged to make a yearly declaration as to his or her income. The average annual amount of these pensions has been latterly about £2000. Pensions are also given according to the civil service scale to certain officers on retirement. It may be stated here that with the exception of these pensions and of salaries and fees for official services, no member of the Academy derives any pecuniary benefit from the funds of the institution. Donations to distressed artists who are or have been exhibitors at the Royal Academy, their widows and children under twenty-one years of age, are made twice a year in February and August. The maximum amount that can be granted to any one applicant in one donation is £100, and no one can receive a grant more than once a year. The average yearly amount thus expended is from £1200 to £1500. In addition to these charities from its general funds, the Academy administers for the benefit of artists, not members of the Academy, certain other funds which have been bequeathed to it for charitable purposes, viz., the Turner fund, the Cousins fund the Cooke fund, the Newton bequest, and the Edwards fund (*see below*).

Exhibitions.—The source from which have been derived the funds for carrying on the varied work of the Royal Academy, its schools, its charities, and general cost of administration, and which has enabled it to spend large sums on building, and provided it with the means of maintaining the buildings, has been the annual exhibitions. With the exception of the money left by John Gibson, R.A., some of which was spent in building the gallery containing the statues and bas-reliefs bequeathed by him, these exhibitions have provided the sole source of revenue, all other moneys that have come to the Academy having been either left in trust, or been constituted trusts, for certain specific purposes. The first exhibition in 1769 contained 136 works, of which more than one half were contributed by members, and brought in £699: 17: 6. In 1780, the first year in which the receipts exceeded the expenditure, the number of works was 489, of which nearly one-third were by members, and the sum received was £3069: 1s. This increase continued gradually with fluctuations, and in 1836, the last year at Somerset House, the number of works was 1154, and the receipts were £5179: 19s. No great addition to the number of works exhibited took place at Trafalgar Square, but the receipts steadily grew, and their careful management enabled the Academy, when the time came for moving, to erect its own buildings and become no longer dependent on the Government for a home. The greater space afforded by the galleries at Burlington House rendered it possible to increase the number of works exhibited, which of late years has reached a total of over 2000, while the receipts have also been such as to provide the means for further building, and for a largely increased expenditure of all kinds. It may be noted that the number of works sent for exhibition soon began to exceed the space available. In 1868, the last year at Trafalgar Square, the number sent was 3011. This has gone on increasing, with occasional fluctuations, at Burlington House, and the year 1900 saw the maximum, so far, of 13,462. The annual winter exhibition of works by old masters and deceased British artists was begun in 1870. It was never intended to be a source of revenue, but appreciation by the public has so far prevented it from being a cause of loss. The summer exhibition of works by living artists opens on the first Monday in May, and closes on the first Monday in August. The winter exhibition of works by deceased artists opens on the first Monday in January, and closes on the second Saturday in March. The galleries containing the diploma works, the Gibson statuery, and other works of art are open daily, free.

Presidents of the Royal Academy.—Sir Joshua Reynolds, 1768-92; Benjamin West (resigned), 1792-1805; James Wyatt (president-elect), 1805; Benjamin West (re-elected), 1806-20;

Sir Thomas Lawrence, 1820-30; Sir Martin Archer Shee, 1830-50; Sir Charles Lock Eastlake, 1850-65; Sir Francis Grant, 1866-78; Frederick, Lord Leighton of Stretton, 1878-96; Sir John Everett Millais, Bart., 1896; Sir Edward John Poynter, 1896.

The total number of academicians elected since the foundation, exclusive of the 36 original members, is 192, of whom 114 received their art education in the Academy schools. The total number of associates elected since the foundation, who have not reached the higher grade, inclusive of the 30 now living, is 103, of whom 46 received their art education in the Academy schools.

The total number of students admitted since 1769 is 4697, making a yearly average of about 36. The number at present on the books is 172.

The library contains about 7000 volumes, dealing with the history, the theory, and the practice of the various branches of the fine arts, some of them of great rarity and value. It is open daily to the students and members, and to other persons on a proper introduction.

The trust funds administered by the Royal Academy are:—

The *Turner fund* (J. M. W. Turner, R.A.), which provides sixteen annuities of £50 each, for artists of repute not members of the Academy, also a biennial scholarship of £50 and a gold medal for a landscape painting.

The *Chantrey fund* (Sir Francis Chantrey, R.A.), the income of which, paid over by the Chantrey trustees, is spent on pictures and sculpture.

The *Creswick fund* (Thomas Creswick, R.A.), which provides an annual prize of £30 for a landscape painting in oil.

The *Cooke fund* (E. W. Cooke, R.A.), which provides two annuities of £35 each, for painters not members of the Academy, over sixty years of age and in need.

The *Landseer fund* (Charles Landseer, R.A.), which provides four scholarships of £40 each, two in painting and two in sculpture, tenable for two years, open to students at the end of the first two years of studentship, and given for the best work done during the second year.

The *Armitage fund* (E. Armitage, R.A.), which provides two annual prizes of £30 and £10, for a design in monochrome for a figure picture.

The *Cousins fund* (S. Cousins, R.A.), which provides seven annuities of £80 each for deserving artists, not members of the Academy, in need of assistance.

The *Newton bequest* (H. C. Newton), which provides an annual sum of £60 for the indigent widow of a painter.

The *Bizo fund* (John Bizo), to be used in the scientific investigation into the nature of pigments and varnishes, &c.

The *Edwards fund* (W. J. Edwards), producing £40 a year for the benefit of poor artists or artistic engravers.

The *Leighton bequest* (Lord Leighton, P.R.A.), received from Mrs Orr and Mrs Matthews in memory of their brother, the income from which, about £300, is to be expended on the decoration of public places and buildings.

The literature concerning the Royal Academy consists chiefly of pamphlets and articles of more or less ephemeral value. More serious works are: WILLIAM SANDBY. *The History of the Royal Academy of Arts*. London, 1862 (withdrawn from circulation on a question of copyright).—*Report from the Select Committee on Arts and their Connexion with Manufactures, with the Minutes of Evidence and Appendix*. London, 1836.—*Report of the Royal Commission on the Royal Academy, with Minutes of Evidence and Appendix*. London, 1863.—MARTIN ARCHER SHEE. *The Life of Sir M. A. Shee, P.R.A.* London, 1860.—C. R. LESLIE, R.A. and TOM TAYLOR. *Life and Times of Sir Joshua Reynolds, P.R.A.* London, 1865.—J. E. HODGSON, R.A. (the late), and FRED. A. EATON, Sec. R.A. "The Royal Academy in the Last Century," *Art Journal*, 1889-91. But the chief sources of information on the subject are the minute-books of the council, and of the general assembly, and the annual reports, which, however, only date from 1859.

Accident. See INSURANCE.

Account, a term used chiefly on the Stock Exchange to designate either the periodical settlement itself or the interval between one periodical settlement and the next. In most securities the transactions which have been effected are settled twice a month. For transactions in consols and a few kindred securities, such as India stocks, the regular settlement occurs only once a month, but a considerable part of the business in them is done "for cash," i.e., for settlement immediately. For most securities except mining shares the settlement extends over three

days, the account or settlement in mining shares occupying four days. The first of these days is called the "carrying-over" or "making-up" day, and is employed in adjusting the accounts open between the class of speculators known as "bulls," who buy securities for which they do not wish to pay in the hope of selling them before the settlement at higher prices, and that known as "bears," who sell securities which they do not possess in the hope of buying them before the settlement at lower prices. The second day, where there are three, and the second and third days, where there are four, are the "ticket days" or "name days," when purchasers of registered securities pass to the sellers tickets setting forth the names into which the same are to be transferred. The last is the "pay day," "settling day," or "account day," when money balances, or "differences," have to be met, and brokers who have purchased securities must be prepared to pay for them on delivery. Much of the work of the Stock Exchange account is carried out by a department of that institution corresponding to the bankers' clearing house. Its function is to bring into direct communication the ultimate buyer and the ultimate seller as represented by their respective brokers, thus eliminating, for the purposes of the settlement, the middleman known as the "dealer" or "jobber." The further returns of the bankers' clearing house, concerning which, in illustration of the financial importance of the account, figures were given in the ninth edition of the *Encyclopædia Britannica* (i. 91) down to 1873, are as follows:—

	On Fourths of the Month.	On Stock Exchange Account Days.	On Consols Settling Days.
1873	£272,156,000	£1,038,257,000	£249,755,000
1874	265,427,000	1,010,456,000	260,244,000
1875	245,810,000	1,043,464,000	251,572,000
1876	225,936,000	761,091,000	225,948,000
1877	232,630,000	744,085,000	228,254,000
1878	217,753,000	795,443,000	227,241,000
1879	213,348,000	842,937,000	225,381,000
1880	236,809,000	1,151,867,000	255,224,000
1881	253,133,000	1,383,430,000	278,864,000
1882	238,150,000	1,228,916,000	278,387,000
1883	239,080,000	1,058,763,000	254,620,000
1884	242,659,000	960,623,000	268,352,000
1885	221,873,000	935,084,000	249,327,000
1886	215,519,000	1,198,557,000	263,497,000
1887	256,469,000	1,145,842,000	297,199,000
1888	272,091,000	1,252,466,000	332,470,000
1889	290,117,000	1,338,842,000	351,690,000
1890	289,107,000	1,416,543,000	358,598,000
1891	264,501,000	1,067,403,000	314,807,000
1892	260,422,000	1,022,764,000	299,405,000
1893	268,084,000	1,002,664,000	300,478,000
1894	261,547,000	964,455,000	301,448,000
1895	283,610,000	1,304,679,000	345,446,000
1896	290,681,000	1,162,866,000	380,354,000
1897	302,123,000	1,113,682,000	362,610,000
1898	331,267,000	1,231,247,000	402,861,000
1899	359,088,000	1,544,295,000	403,042,000
1900	372,463,000	1,339,571,000	438,125,000

(S. D. H.)

Accountants.—The term "accountant" is one to which, of late years, its original meaning has been more generally attributed—that of an expert in the science of book-keeping. It is sometimes adopted by book-keepers, but this is an erroneous application of the term; it properly describes those competent to design and control the systems of accounts required for the record of the multifarious and rapid transactions of trade and finance. It assumes the possession of a wide knowledge of the principles upon which accountancy is based, which may be shortly described as constituting a science by means of which all mercantile and financial transactions, whether in money or in money's worth, including operations completed and

engagements undertaken to be fulfilled at once or in a future, however remote, may be recorded; and this science comprises a knowledge of the methods of preparing statistics, whether relating to finance or to any transactions or circumstances which can be stated by numeration, and of ascertaining or estimating on correct bases the cost of any operation whether in money, in commodities, in time, in life, or in any wasting property. Generally, accountancy may be described as being the science by means of which all operations, as far as they are capable of being shown in figures, are accurately recorded and their results ascertained and stated.

The origin of the profession of accountancy in Great Britain is difficult to trace; auditors of accounts were

History.

naturally of very early existence, being mentioned as officers of importance in the statutes of Westminster in the reign of Edward I. The art of accountancy on a scientific principle must certainly have been understood in Italy before 1495, when Friar Lucas de Borgia published at Venice his treatise on book-keeping; but the first known English book on the science was published in London by John Gouge or Gough in 1543. It is described as *A Profitable Treatise called the Instrument or Booke to learn to knowe the good order of the keepyng of the famous reconyng, called in Latin, Dare and Habere, and, in Englyshe, Debitor and Creditor*. A short book of instruction was also published in 1588 by John Mellis of Southwark, in which he says, "I am but the renuer and reviver of an auncient old copie printed here in London the 14 of August 1543: collected, published, made, and set forth by one Hugh Oldcastle, Scholemaster, who, as appeareth by his treatise, then taught Arithmetike, and this booke in Saint Ollaves parish in Marke Lane." John Mellis refers to the fact that the principle of accounts he explains (which is a simple system of double entry) is "after the forme of Venice." The very interesting and able book described as *The Merchants Mirrour, or directions for the perfect ordering and keeping of his accounts; framed by way of Debitor and Creditor, after the (so tearmed) Italian manner*, by Richard Dafforne, accountant, published in 1635, contains many references to early books on the science of accountancy. In a chapter in this book, headed "Opinion of Book-keeping's Antiquity," the author states, on the authority of another writer, that the form of book-keeping referred to had then been in use in Italy about two hundred years, "but that the same, or one in many parts very like this, was used in the time of Julius Cæsar, and in Rome long before." He gives quotations of Latin book-keeping terms in use in ancient times, and refers to "ex Oratione Ciceronis pro Roscio Comædo"; and he adds: "That the one side of their booke was used for Debitor, the other for Creditor, is manifest in a certaine place, Naturalis Historiæ Plinii, lib. 2, cap. 7, where hee, speaking of Fortune, saith thus:

Huic Omnia Expensa,
Huic Omnia Feruntur accepta et in tota Ratione mortalium sola
Utramque Paginam facit."

An early Dutch writer appears to have suggested that double entry book-keeping was even in existence among the Greeks, pointing to scientific accountancy having been invented in remote times.

There were several editions of Richard Dafforne's book printed—the second edition having been published in 1636, the third in 1656, and another was issued in 1684. The book is a very complete treatise on scientific accountancy, it was beautifully prepared and contains elaborate explanations; the numerous editions tend to prove that the science was highly appreciated in the 17th century. From this time there has been a continuous supply of literature on the subject, many of the authors styling

themselves accountants and teachers of the art, and thus proving that the professional accountant was then known and employed. Very early in the 18th century the services of an accountant practising in the City of London were made use of in the course of an investigation into the transactions of a director of the South Sea Company, who had been dealing in the Company's stock. During this investigation the accountant appears to have examined the books of at least two firms of merchants. His report is described *Observations made upon examining the books of Sawbridge and Company*, by Charles Snell, Writing Master and Accountant in Foster Lane, London.

In 1799, when Holden's *Triennial Directory of London, Westminster, and Southwark* was first published, 11 individuals and firms were therein described as accountants; in the same Directory, for the period 1809-11, the number had risen to 24; and in that for 1822-24, there were 73 firms of practising accountants recorded.

It will be noticed that the English books dealing with scientific book-keeping, to which reference has been made, were written at a time when the English and Dutch were very actively engaged in foreign trade, in succession to the Italian merchants of the 14th, 15th and 16th centuries; but it was not until the beginning of the 19th century that, in consequence of the adoption of improved methods of manufacture and transit, resulting from the application of water and steam power to manufactures and methods of conveyance which largely increased the trade of Great Britain, the profession of an accountant became one which men of scientific knowledge and capacity adopted for their business career. Corporations and companies were formed to carry out large operations previously either left to the State or not undertaken, and for the development of trades and manufactures which were becoming less profitable when carried on by hand labour and with limited capital; and, for these, the services of public accountants were necessarily required to devise systems of accounts and methods of control, and to enable the results of the various transactions carried on to be ascertained with the least waste of power or chance of loss by negligence or fraud. The large number of companies formed in 1843 and 1844, when a great amount of capital was invested in railways and extensive speculation resulted, also added to the demand for the services of professional accountants. The Companies' Clauses Consolidation Act made provision for the audit of the accounts of companies regulated by Act of Parliament and gave some extensive powers to the auditors, who are now, to a very large extent, selected from among professional accountants. The Companies Act of 1862 led to a large extension of the business of accountants, both as auditors and liquidators of companies; and the Acts relating to bankruptcy passed between the years 1831 and 1883 added to the work devolving on professional accountants. The Companies Act 1879, which affected banking companies, made provision for the audit of their accounts, and it has been found desirable, in most cases, to appoint professional accountants to this duty. The experience and professional knowledge of trained accountants have, in fact, been utilized by their appointment as auditors in the majority of joint-stock companies, whether manufacturing, banking, trading, or created for any other purpose. Until the Companies Act 1900 was passed there was no general obligation upon limited companies to have auditors; this Act not only requires that auditors shall be appointed in all cases, but provides for their remuneration, and to a limited extent defines their rights and duties. This modification of the law relating to companies will doubtless have a beneficial effect upon their management,

Modern
develop-
ment.

as it provides a very necessary control upon the operations of directors, and enables the shareholders to obtain an independent opinion on the transactions and position of the companies in which they are interested. The Legislature evidently did not find it easy to formulate at all clearly the duties of auditors, and it seems reasonable to suppose that any general definition will prove an impossibility, as the work which auditors undertake must vary very widely, and depends largely upon the scope of the operations the accounts of which are to be examined; at the same time, the provisions made mark a distinct advance in company law, and will probably create a considerable increase in the demand for the services of accountants.

The duties of practising accountants cover a very wide area: they act as trustees, liquidators, receivers, and managers of businesses, the owners of which are in default or their affairs in liquidation, both under the direction of the courts and by appointment of creditors and others; they are largely engaged as arbitrators, umpires, and referees in differences relating to matters of account or finance; they prepare the accounts of executors and trustees, and the necessary statements of affairs in cases of bankruptcy, both of firms and companies; they prepare accounts for prosecutions in cases of fraud and misconduct; and they are constantly called upon to unravel and properly state the accounts of complicated transactions. Their services are commonly required to certify the profits of businesses intended to be sold, either privately or to companies by means of a published prospectus; and, in cases of compulsory purchases of businesses by railway companies and public bodies, the statements of the profits of the businesses to be acquired are generally made by them. In a very large number of financial operations they are called upon to give advice and prepare accounts, and in few business matters requiring arithmetical calculations or involving the investigation of figures, and particularly where a considerable acquaintance with the principles of law is needed, are their services not utilized. One of the most important duties undertaken by accountants is the audit of accounts, and this duty has, of late years, been widely extended. Originally, auditors were appointed to examine and vouch statements of receipts and payments; but the provisions made in Acts of Parliament in relation to audit, and the requirements of most articles of association of limited

Auditors. companies put much graver responsibilities on auditors, who are now generally required to certify to the accuracy of balance sheets and of revenue and other accounts, the performance of which duties involves far more knowledge of accounts than was once required. The efficiency, in most cases, of audits conducted by skilled accountants has led the public to attach exceptional value to their audit certificates, and to demand extensive knowledge and ability in the conduct of the audit of the accounts of public companies. One other requirement which is generally regarded as indispensable, is that the work of audit should be very expeditiously performed; for it is easy to understand that, were the presentation of the accounts of a company and the distribution of dividends materially delayed in consequence of the audit, much inconvenience would result, while the value of the criticism of the accounts of business operations would be much deteriorated if it could not be made very shortly after the accounts were closed. In these circumstances, in the cases of large concerns with wide ramifications and numerous transactions, it is necessary that auditors should have the help of trained assistants, and thus the personal examination of details by the auditor himself is, to a large extent, rendered unnecessary and the cost of audit materially re-

duced. This delegation of duty by auditors is generally well understood, and is in accordance with the requirements of those concerned; but there has been a tendency of late years to enlarge the responsibilities of auditors to an extent which, if persisted in, might render it dangerous for men of reputation and means to accept the duties. It is to be hoped that future legislation may, on the one hand, secure the faithful performance of difficult work by competent men; and, on the other, not leave an auditor responsible to the extent of his means either for some carelessness on the part of a clerk, or for an inaccurate decision at a time of pressure on a matter respecting which he is probably unable to obtain competent advice without disclosing that which it is his duty to keep secret.

While the number of practising accountants has of late years been steadily increasing and their services are correspondingly appreciated, the necessity for controlling those exercising the profession and for improving its status has naturally become **Organization.** apparent. The first important steps in this direction were taken by the accountants in Scotland—the Society of Accountants in Edinburgh being incorporated by royal charter in 1854; similar societies in Glasgow and Aberdeen being also incorporated by charter in 1855 and 1867. The Institute of Accountants was formed in London in 1870, but did not receive a royal charter until the 11th May 1880, when all the then existing accountants' societies and institutes in England were incorporated as the Institute of Chartered Accountants in England and Wales, and means were provided by which all the then practising accountants in these countries could claim membership thereof. In the year 1885 the Society of Accountants and Auditors was incorporated, but has obtained no charter; this body, while numbering among its members a considerable number of practising accountants in the United Kingdom, also includes treasurers and accountants to cities and boroughs in England, as well as clerks to chartered and other accountants. A large proportion of its members also consists of accountants practising abroad. In 1888 an Institute of Chartered Accountants was formed in Ireland, and a great many institutes and societies have been formed in the British colonies and in the United States, some of which have local charters. It is curious to note, however, that, outside the United Kingdom, it was only in the British colonies, and lately in America, that associations of practising accountants existed, until, in 1895, an Institute of Accountants was founded in Utrecht for Dutch accountants; when, although the principles of accountancy have been well understood and practised in Holland since the 16th century, and probably earlier, it was found necessary to borrow the words "accountant" and "accountancy" from the English language to convey to the Dutch an idea of the meaning of the terms.

The Institute of Chartered Accountants in England and Wales, on the 1st June 1900, numbered 3195 members, of whom 2469 were practising in England and Wales, and 119 were practising abroad; the majority of the other members (607) having passed the qualifying examinations of the Institute. In the three chartered bodies in Scotland there were, at the end of 1899, 698 members, of whom about four-fifths were in practice; and the Irish Institute numbered 50 members, of whom 42 were in practice. The list of 1344 members of the Society of Accountants and Auditors in the United Kingdom, dated June 1900, does not enable a classification to be made between those practising as accountants and those otherwise engaged; but it may fairly be assumed that about five-eighths of this number were practising. Making

an allowance for public accountants who are not members of any of the institutes and societies mentioned above, it would appear that about 4000 persons were, at the beginning of the year 1900, practising as public accountants in the United Kingdom.

Accra. See GOLD COAST.

Accrington, a municipal borough (1878), in the

Accrington parliamentary division of Lancashire, England, 19 miles N. of Manchester by rail. Modern erections are Established, Free, Congregational, Baptist, and Methodist churches, and a municipal technical school. Dye-works, chemical manufactures, and manufactures of machinery for the cotton-mills have been established. Area, 3425 acres. Population in 1881, 31,435; in 1891, 38,603; in 1901, 43,076.

ACCUMULATORS.

THE early study of electrolysis made scientific men acquainted with what were called secondary currents and polarization. The former were first used by Grove, whose gas battery may be called the first accumulator; but systematic search for the best effects was not undertaken till 1859, when Planté began a masterly and fruitful investigation. He soon produced his well-known battery, a cell with higher electromotive force and greater current-yielding power than any other practical combination. He obtained these results by putting lead plates into dilute sulphuric acid and sending a current through; after a few reversals he found one plate to be covered by peroxide of lead, the other with a porous mass of lead. He set himself to *accumulate* energy in the cell, by which he meant the formation of a quantity of the active materials. The names given to Planté's first cell have been frequently misunderstood. The terms secondary battery, storage battery, and accumulator have been taken to indicate that there was an accumulation or storage of electricity or of electric current; but the error is not Planté's, as is clear from his declaration that his couple is able to give discharges of long duration, or to retain its charge for a long time, "et d'emmagasiner ainsi le travail chimique de la pile voltaïque." The value of the cell arises from a happy combination of properties. The three active materials are peroxide of lead, spongy metallic lead, and dilute sulphuric acid. Of these, the peroxide is an excellent depolarizer; the lead is a sufficiently good electro-positive metal; and the dilute sulphuric acid has a very high conductivity for an electrolyte. Moreover, the two solid substances are not only themselves insoluble in the dilute acid, but the sulphate of lead formed from them in the course of discharge is also insoluble. Consequently, it remains fixed in the place where it is formed; and on the passage of the charging current, the original PbO_2 and Pb are reproduced in the places they originally occupied. Thus there is no material change in the distribution of masses of active material. Lastly, the active materials are in a porous, spongy condition, so that the acid is within reach of all parts of them. The resistance of the cell is low, while the energy of the chemical action to which it gives rise imparts a high electromotive force.

Planté carefully studied the changes which occur in the formation, charge, and discharge of the cell. In forming, he placed two sheets of lead in sulphuric acid, separating them by narrow strips of caoutchouc (Fig. 1).

When a charging current is sent through the cell, the hydrogen liberated at plate A escapes, a small quantity possibly being spent in reducing the surface film of oxide generally found on lead. Some of the oxygen is always fixed on the positive plate B, forming a surface film of peroxide. After a few minutes the current is reversed, plate A is peroxidized, while the peroxide previously formed on B is reduced to metallic lead in a spongy state. By repeated reversals, the surface of each plate is alternately peroxidized and reduced to metallic lead. In successive oxidations, the

action penetrates farther into the plate, furnishing each time a larger quantity of spongy PbO_2 on one plate and of spongy lead on the other. It follows that the duration of the successive charging currents also increases. At the beginning, a few minutes suffice; at the end, many hours are required. After the first six or eight cycles, Planté allowed a period of repose before reversing. He claimed that the PbO_2 formed by reversal after repose was more strongly adherent, and also more crystalline, than if no repose were allowed. The following figures show the relative amounts of oxygen absorbed by a given plate in successive charges (between one charge and the next the plate stood in repose for the time stated, then was reduced, and again charged as anode):—

Separate Periods of Repose.	Charge.	Relative Amount of Peroxide formed.
...	First	1.0
18 hours	Second	1.57
2 days	Third	1.71
4 "	Fourth	2.14
2 "	Fifth	2.43

and so on for many days.—(Gladstone and Tribe, *Chemistry of Secondary Batteries*). Seeing that each plate is in turn oxidized and then reduced, it is evident that the spongy lead will increase at the same rate on the other plate of the cell. The process of "forming" thus briefly described was not continued indefinitely, but only till a fair proportion of the thickness of the plates was converted into the spongy material, PbO_2 and Pb respectively. After this, reversal was not permitted, the cell being put into use and always charged in a given direction. If the process of forming by reversal be continued, the positive plate is ultimately all converted into PbO_2 and falls to pieces.

Planté made excellent cells by this method, yet three objections were urged against them. They required too much time to "form"; the spongy masses (PbO_2 more especially) fell off for want of mechanical support, and the separating strips of caoutchouc were not likely to have a long life. The first advance was made by Faure (1881), who greatly shortened the time required for "forming" by giving the plates a preliminary coating of red lead, whereby the slow process of biting into the metal was avoided. At the first charging, the red lead on the + electrode is changed to PbO_2 , while that on the - electrode is reduced to spongy lead. Thus one continuous operation, lasting perhaps sixty hours, takes the place of many reversals, which, with periods of repose, last as much as three months. Faure used felt as a separating membrane, but its use was soon abolished by methods of construction due to Volckmar, Sellon, Swan, and others. These inventors put the paste not on to plates of lead, but into the holes of a grid, which, when carefully designed, affords good mechanical support to the spongy masses and does away with the necessity for felt, &c. They are more satisfactory, however, as supporters of spongy lead than of the peroxide, since at the point of contact in the latter case the acid gives rise to a local action, which slowly destroys the grid. Disintegration follows sooner or later, though the best makers are able to defer the failure for a fairly long time. Efforts have been made by Tribe, Fitzgerald, and others to dispense with a supporting grid for the positive plate, but these attempts have not yet been successful enough to enable them to compete with the other forms.

The following description of well-known forms of cells will illustrate the methods adopted at the present time.

Planté Type.—"Chloride Accumulator" cells derive their name from the fact that chloride of lead is used in making the negative plates. There is no chlorine or chloride in the cell when ready for use. For the negative plates, the chloride of lead is melted in large iron pans at a temperature of about $600^{\circ} C.$, and then carried by plumbago crucibles to a

Chloride accumulators.

Fig. 1.

mould, where it is cast into short hexagonal prisms or pastilles. These are arranged in the bottom half of a plate mould, the top half of which is permanently fixed

Fig. 2.

zinc solution, when the zinc takes chlorine from the lead chloride, and leaves the metallic lead in a finely-divided, porous condition in the space previously occupied by the chloride. After several washings, the plate is made a negative pole in sulphuric acid for a little while, to ensure absolute freedom from chlorine, and is then ready for use. Fig. 2 shows the negative plate in position in a cell. The holes in the hexagonal plugs are to facilitate diffusion of acid. For the positive plates, lead grids are first cast under pressure, the mould being arranged to give a plate of lead 0.4 inch thick, pierced by a number of circular holes about half an inch in diameter with slight counter-sinks on the faces. Into each of these holes is thrust a roll or rosette of lead ribbon, which has first been cut to the right breadth (equal to the thickness of plate), then ribbed or gimped, and finally coiled into a rosette. The rosettes have sufficient spring to fix themselves in the circular holes of the lead plate, but are keyed into position by putting the plate through a hydraulic press. The plates are then put into tanks with temporary negatives, and a current is passed for a long time, whereby the rosettes become coated with a fine adherent hard crystalline peroxide. The cell can be discharged at very high rates; one square foot of plate will, give a current of 40 amperes when necessary.

A second cell of the Planté type is that known as the "D.P." Its construction is very simple (Fig. 3). A number of corrugated lead strips, about one quarter of an inch wide, are piled to a height of 7 or 8 inches, and their ends are burned together.

Thus a plate is formed through which the acid can easily pass. A number of such plates are joined together to form the positives, the negatives being formed by pasting a somewhat similar framework with litharge. Having put the two sets of plates into the cells, a prolonged charging current is sent through; the litharge is reduced to spongy lead, and the surface of the corrugated strips

which form the positive plate becomes covered with peroxide.

In the "Monobloc" cell, the general appearance and arrangement of which are shown in Fig. 4, the positive block is built up of corrugated sheets of lead, perforated by rectangular holes. When these "Monobloc" cell. perforated sheets have been laid on each other to a height of about 9 inches, and the four corners burned to stout lead fillets, a very compact block is obtained, to all parts of which acid is able easily to penetrate. The negative plate consists of a series of rods, each having a lead core on which lies spongy lead. These are burned to a lug at the top, and each rod being enclosed in a per-

Fig. 3.

Fig. 4.

forated ebonite sheath the whole is put into the perforations of the positive blocks. These cells have been used on the tramway cars at Ghent and other places on the Continent.

Pasted Types.—The best-known cell of this type is the E.P.S. cell, made by the Electric Power Storage Company. The paste for the positive plates is a mixture of red lead with sulphuric acid, and for the negative plates litharge is used instead of red lead. Different forms of grids are adopted, according to the special pur-

Fig. 5.

Fig. 6.

pose for which the cells are intended. For ordinary isolated installations, the grid wall has a section shown in Fig. 5, the holes *h*, as seen from the direction of the arrow, being square and slightly larger on the negative than on the positive grid. For rapid discharges (up to two hours) the negative grid is much the same, except that the holes

are rectangular and the plate is thicker. The positive grid has quite a different shape (Fig. 6). For the quickest discharges (up to one hour or less) the grid has the form of thin vertical ribs $\frac{1}{10}$ inch apart, strengthened at intervals by horizontal ribs. Between the vertical ribs are deep narrow grooves, which hold the active material. The negative grid is like Fig. 5, the holes being rectangular in shape.

Fig. 7.

Fig. 7 shows the general appearance of the two-hour discharge cell, illustrating the method of connecting, and the greater thickness of the positive over the negative plate; also, the clearance between the plates and the bottom of the cell. There are other types of grids besides those mentioned, to suit the varying conditions of electrical work, for high discharge, traction, &c.

Another cell of pasted type is that known as the "Hart" accumulator. The positive and negative plates, which are similar in size and shape, are pasted with red lead and litharge respectively. The grid is in the form of lattice-work, arranged alternately on either side, with strong leaden ribs running diagonally across the plate. The active material in each plate is split up into a number of small pellets, each of which is gripped

Fig. 8.

hard on its surface by means of a leaden lip attached to the grid and turned over by a special process. In joining up, a special terminal is used. The lugs are first faced up against each other and tightened by a temporary master connector. This then gives way to a non-corrosive bolt,

which is conically tapered and gives a large connecting surface. Fig. 8 gives a view of the cells and also of the connector.

Mixed Type.—In this type, of which the "Tudor" cell is a well-known example, the positives are prepared by a pure Planté formation from a carefully-made lead casting, and the negatives by pasting. Fig. 9 shows the unformed positive plate. A mould is made by supporting narrow gun-metal racks on each side of a cast-iron frame. The teeth of the racks form vertical grooves in the faces of the casting; and as narrow spaces are left between one rack and the next

lower or higher one, horizontal ribs are seen. To give greater strength, thicker vertical ribs are obtained by cutting out one tooth of each rack at intervals. The grooves are about $\frac{1}{8}$ inch apart and $\frac{1}{4}$ inch deep. The positive plates are about $\frac{1}{2}$ inch thick, and are formed (that is, covered with peroxide) by charging them, and leaving them on open circuit (repose) alternately. Later, charging and discharging are substituted. Here, as in Planté's work, charging and discharging become more prolonged as the formation proceeds. As much as five or six weeks is required. The negative plate is a pasted plate. Litharge mixed with sulphuric acid is placed in the holes of a lead grid, to which, before pasting, is given a superficial coating of peroxide by making it a terminal in an acid bath and charging it as a positive for a short time. This gives a greater attachment between the grid and the spongy lead when subsequently reduced. The negative plate is about $\frac{4}{10}$ inch thick.

There are many other types of cells. An interesting one is that known as the Lithanode. Originally, this was an attempt to prevent local action by making the positive of peroxide alone, and to form it so slowly that its mechanical arrangement and strength would facilitate diffusion and prevent disintegration. It has not yet been largely used.

Whatever the type of cell may be, it is important to attend to the following working requirements:—(1) The cells must be fully equal to the maximum demand, both in discharge rate and capacity. (2) All the cells in one series ought to be equal in discharge rate and capacity. This involves similarity of treatment. (3) The cells are erected on strong wooden stands. Where floor space is too expensive, they can be erected in tiers; but if possible this should be avoided. They ought to lie in rows, so arranged that it is easy to get to one side (at least) of every cell, for examination and testing, and if need be to detach and remove it or its plates. Where a second tier is placed over the first, sufficient clearance space must be allowed for the plates to be lifted out of the lower boxes. The cells are insulated by supporting them on glass or mushroom-shaped oil insulators. If the containing vessels are made of glass, it is desirable to put them in wooden trays which distribute the weight between the vessel and insulators. To prevent acid spray from filling the air of the room, a glass plate is arranged over each cell. The positive and negative sections are fixed in position with insulating forks or tubes, and the positive terminal of one cell is joined to the negative of the next by burning or bolting. If the latter method is adopted, the surfaces ought to be very clean and well pressed home. The joint ought to be covered by vaseline or varnish. When this has been done, examination ought to be made of each cell to see that the plates are evenly spaced, that the separators (glass tubes or ebonite forks between the plates) are in position and vertical, and that there are no scales or other adventitious matter connecting the plates. The floor of the cell ought to be quite clear; if anything lies there it must be removed. (4) To mix the solution a *gentle stream* of sulphuric acid must be poured into the water (not the other way, lest too great heating cause an accident). It is necessary to stir the whole as the mixing proceeds and to arrange that the density is

Fig. 9.

about 1190, or according to the recommendation of the maker. About five volumes of water ought to be taken to one volume of acid. After mixing, allow to cool for two or three hours. The strong acid ought to be free from arsenic, copper, and other similar impurities. The water ought to be as pure as can be obtained, distilled water being best; rain water is also good. If potable water be employed, it will generally be improved by boiling, which removes some of the lime held in solution. The impurity in ordinary drinking water is very slight; but as all cells lose by evaporation and requires additions of water from time to time, there is a tendency for it to increase. The acid must not be put into the cells till everything is ready for charging. (5) A shunt-wound or separately-excited dynamo being ready and running so as to give at will 2.6 or 2.7 volts per cell, the acid is run into the cells. As soon as this is done, the dynamo must be switched on and charging commenced. The positive terminal of the dynamo must be joined to the positive terminal of the battery. If necessary, the + end of the machine must be found by a trial cell made of two plain lead sheets in dilute acid. It is important also to maintain this first charging operation for a long time without a break. Twelve hours is a minimum time, twenty-four not too much. The charging is not even then complete, though a short interval is not so injurious as in the earlier stage. The full charge required varies with the cells, but in all types a full and practically continuous first charge is imperatively necessary. During the early part of this charge the density of the acid may fall; but after a time ought to increase, and finally reach the value desired for permanent working. Towards the end of the "formation" vigilant observation must be exercised. It is important to notice whether any cells are appreciably behind the others in voltage, density, or gassing. Such cells may be faulty, and in any case they must be charged and tended till their condition is like that of the others. They ought not to go on the discharge circuit till this is assured. The examination of the cells before passing them as ready for discharge includes:—(a) Density of acid as shown by the hydrometer. (b) Voltage. This may be taken when charging or when idle. In the first case it ought to be from 2.4 to 2.6 volts, according to conditions. In the second case it ought to be just over 2 volts, provided that the observation is not taken too soon after switching off the charging current. For about half an hour after that is done, the E.M.F. has a transient high value, so that, if it be desired to get the proper E.M.F. of the cell, the observation must be taken thirty minutes after the charging ceases. (c) Eye observations of the plates and the acid between them. The positive plates ought to show a rich dark brown colour, the negatives a dull slate blue, and the space between ought to be quite clear and free from anything like solid matter. All the positives ought to be alike, and similarly all the negatives. If the cells show similarity in these respects, they will probably be in good working order.

As to management, it is important to keep to certain simple rules, of which these are the chief:—(1) Never discharge below a potential difference of 1.85 (or in rapid discharge, 1.8) volt. (2) Never leave the cells discharged, if it be avoidable. (3) Give the cells a special full charging once a month. (4) Make a periodic examination of each cell, determining its E.M.F., density of acid, the condition of its plates, and freedom from growth. Any incipient growth, however small, must be carefully watched. (5) If any cell shows signs of weakness, keep it off discharge till it has been brought back to full condition. See that it is free from any connexion between the plates which would cause shortcircuiting; the frame or support which carries the plates sometimes gets covered by a conducting layer. To restore the cell, two methods can be adopted. In private installations it may be disconnected and charged by one or two cells reserved for the purpose; or, as is preferable, it may be left in circuit, and a cell in good order put in parallel with it. This acts as a "milking" cell, not only preventing the faulty one from discharging, but keeping it supplied with a charging current till its P.D. is normal. Every battery attendant should be provided with a hydrometer and a voltmeter. The former enables him to determine from time to time the density of the acid in the cells; instruments specially constructed for the purpose are now easily procurable, and it is desirable that one be provided for every 20 or 25 cells. The voltmeter should read up to about 3 volts and be fitted with a suitable connector to enable contacts to be made quickly with any desired cell. A portable glow lamp should also be available, so that a full light can be thrown into any cell; a frosted bulb is rather better than a clear one for this purpose. He must also have some form of wooden scraper to remove any growth from the plates. The scraping must be done gently, with as little other disturbance as possible. By the ordinary operations which go on in the cell, small portions of the plates become detached. It is important that these should fall below the plates, lest they shortcircuit the cell, and therefore sufficient space ought to be left between the bottom of the plates and the floor of the cell for these "scalings" to accumulate without touching the plates. It is desirable that they be disturbed as little

as possible till their increase seriously encroaches on the free space. It sometimes happens that brass nuts or bolts, &c., are dropped into a cell; these should be removed at once, as their partial solution would greatly endanger the negative plates. The level of the liquid must be kept above the top of the plates. It may sometimes be necessary to replenish the solution with some dilute acid, but strong acid must never be added.

The chief faults are buckling, growth, sulphating, and disintegration. Buckling of the plates generally follows excessive discharge, caused by abnormal load or by accidental shortcircuiting. At such times asymmetry in the cell is apt to make some part of the plate take much more than its share of the current. That part then expands unduly, as explained later, and curvature is produced. The only remedy is to remove the plate, and press it back into shape as gently as possible. Growth arises generally from scales from one part falling on some other; say, on the negative. In the next charging the scale is reduced to a projecting bit of lead, which grows still further because other particles rest on it. The remedy is, gently to scrape off any incipient growth. Sulphating, the formation of a white hard surface on the active material, is due to neglect or excessive discharge. It often yields, if a small quantity of sulphate of soda be added to the liquid in the cell. Disintegration is due to local action, and there is no ultimate remedy. The end can be deferred by care in working, and by avoiding strains and excessive discharge as much as possible.

Accumulators contain only three active substances—spongy lead on the negative plate, spongy peroxide of lead on the positive plate, and dilute sulphuric acid between them. It will be shown later that a fourth substance, sulphate of lead, is formed on both plates during discharge, and also, though to a small extent, during repose. *Spongy lead* looks much like ordinary lead. Its colour is a blue gray, density probably similar to that of lead, 11.3, and its electric resistance .0000195 ohm between opposite faces of a cubic centimetre. *Spongy peroxide of lead* is a dark brown crystalline powder, with a density of 9.28. Its electric conductivity has been determined by J. Shields (*Chemical News*, 65, 87). The hydrated peroxide prepared by purely chemical methods had a specific resistance of 5.59×10^9 c.g.s. units (=5.59 ohms); but a similar hydrate, prepared electrolytically, gave slightly higher figures, 6.78×10^9 c.g.s., or 6.78 ohms. Both forms of this substance conduct metallically, and neither of them electrolytically. *Sulphate of lead* is a white powder, with a density of 6.3. Its electric conductivity is so low that it may be classed as a non-conductor. The densities of these three solids being known, it is easy to follow the changes in volume which accompany the formation of sulphate of lead on either plate. One hundred volumes of lead (on the negative plate) form 290 volumes of sulphate, and will therefore require three times as much space as before the action, while 100 volumes of peroxide (on the positive plate) form 186 volumes of sulphate, and will therefore

Accumulators in repose.

FIG. 10.

fill nearly twice as much space as before. These expansion figures are not only important in themselves, but also

throw light on the well-known tendency of the negative plate to run down before the positive. In a given discharge the quantities of sulphate of lead formed on the two lead plates are the same, but the expansion in the lead plugs (and consequent reduction of porosity) is 60 per cent. greater than in the positive plugs. Sulphuric acid is used in the dilute state. The usual density employed is 1.210, which has an electric conductivity of 0.73 c.g.s. units, or a specific resistance of 1.37 ohm for a centimetre cube. The relative conductivity (the reciprocal of resistance) is shown in Fig. 10. From this and the datum just given, the specific resistance of any strength of acid can be found approximately.

There are three kinds of local action:—(1) In all the practical forms of accumulator the positive plate contains two conductors in contact—the lead grid or plate and the peroxide it is intended to support. There exists between them a difference of potential (= 2 volts), and, as the acid touches both, local currents must flow. The course of these will be from a point in the positive grid to the acid, thence to the adjacent peroxide, and back through it to the grid beneath. Such currents involve the formation of sulphate from both the grid and the peroxide, with two definite results: (a) a diminution of the available energy existing as peroxide, and (b) an attack on the lead-supporting surface below. In an early form of accumulator, Gladstone and Tribe found 7 per cent. of sulphate was formed in two hours. Fortunately the sulphate of lead thus formed is insoluble, and covers the free lead surface. Consequently the action becomes very slow after the first hour or so, and would in fact stop altogether if the film of sulphate remained intact, and so prevented access of acid to the lead surface. But in the daily changes of temperature, &c., the strains are great enough to cause some conducting communication, and the local action goes on. This progressive action explains the advantage Planté derived from periods of repose in forming, since it brings a greater quantity of the lead within the reach of the next operation. It also explains the danger which waits on the positive grid or plate, and ultimately leads to its destruction. (2) Local action will arise on the negative plate if a more electro-negative conductor settle on the lead. This sometimes happens because of impurities in the materials used for the paste or existing in the acid. In either case they will find their way to the negative grid or support, and lead to loss of energy and the evolution of hydrogen gas. (Swinburne, *Journ. Inst. Elec. Eng.* 1886.) Even where impurities do not exist in the materials, they are often introduced by small bits of metal being carelessly dropped into the cell. A not unusual habit of engineers is to scrape copper connecting-wires in close proximity to the cells, thus endangering their capacity and life very considerably. Besides this chance of local action on the negative plate, acid of density 1.210 acts directly on the finely-divided lead. Swinburne also drew attention to this in 1886, and indicated its effect on the capacity of the cells, which may be seriously reduced. (3) There is a local action on each of the plates, whenever the acid in one part of the cell differs in density from that in another. This often happens. There is a constant tendency for the acid to get stronger at the bottom of the cell, because during charge the stronger acid brought to the positive plate tends to fall, and in discharge the weaker acid diffusing from the porous plugs of both plates tends to rise. Further still, during charge the acid is strongest in the inner parts of the spongy material, and differences of 25 to 30 per cent. may exist between the inner and outer parts of a plug. A similar difference may exist during discharge, but in this case the acid is strongest on the outside and weakest in the interior. The following table gives the E.M.F.

between a plate of peroxide in weak and another in strong acid; corresponding values are also given for lead plates in acid of different strength (Gladstone and Hibbert, *Journ. Inst. Elec. Eng.* 1892):—

E.M.F. arising from Differences in Strength of Acid.					
Two lead plates.			Two peroxide plates.		
Acid round + lead plate.	Acid round - lead plate.	E.M.F. in volts.	Acid round - PbO ₂ plate.	Acid round + PbO ₂ plate.	E.M.F. in volts.
Per cent.	Per cent.		Per cent.	Per cent.	
0.2	1.35	0.047	0.2	1.35	0.072
"	2.85	0.060	"	2.85	0.095
"	5.5	0.066	"	5.5	0.107
"	10.5	0.082	"	10.5	0.134
"	14.5	0.094	"	14.5	0.150
"	22.5	0.109	"	22.5	0.168
"	36.5	0.150	"	36.5	0.215
"	57.5	0.204	"	57.5	0.359
"	85.5	0.247	"	85.5	0.537
"	98.0	0.266	"	99.0	0.643

The lead in the weaker acid is + to the other; with the peroxide plates the case is reversed. With these figures it is easy to picture the local currents flowing between an inner and an outer part of a single plug during the discharge, owing to the different strength of acid then existing.

The importance of these three kinds of local action arises not so much from the magnitude of the actions they set up as from the special parts of the plates affected by them. Sulphate of lead is formed in each case, but not in the course or path of the regular current. On the positive plate the local action forms sulphate along the interface between the plugs and the grid, and may effectively isolate a large proportion of the peroxide. On the negative plate, when due to deposited copper, &c., it cannot be so definitely followed, but may even give an outside surface coating of sulphate. That arising on both plates by reason of variable acid strength in the

Fig. 11.

plugs cannot be localized, but must necessarily be out of the regular lines of flow of the working currents. It is partly by virtue of these special localizations of the chemical changes that an accumulator seems to be seriously damaged by a rest, whether charged or discharged, and it is a further consequence that subsequent charges only slowly get at this deep-seated sulphate, so that many cycles of work are required to bring back the cell to its earlier value as a working machine.

The electromotive force of a cell varies with the strength of the acid, as may be seen from Fig. 11, taken from Gladstone and Hibbert's paper. The observations with very strong acid were very difficult to obtain; but one good experiment made with

Electromotive force.

98 per cent. acid is marked by x. Streintz (*Ann. Phys. Chem.* 46, p. 449) gives for the E.M.F. the expression

$$E = 1.850 + 0.917 (s - s_0)$$

between the density limits 1.055 and 1.279; $(s - s_0)$ is the excess of the specific gravity of the acid over that of water. It must be understood that the acid referred to in the foregoing curve is that existing in the pores of the spongy masses of the plates. If there be any inequality

Fig. 12.

between that and the acid outside a process of diffusion sets in between them, and the E.M.F. varies so rapidly that no exact measurement can be made. The importance of this diffusion was first pointed out by Duncan and Wiegand (*Electrical World*, N.Y. 1889), who took plates before and after discharge, soaked them in sulphuric acid of 1.175 density, and then transferred them to vessels of distilled water. The acid which diffused out in a given time was estimated, with the result shown in Fig. 12.

The plates contained about 5 grams of acid altogether, so that about one-half diffused out in thirty minutes, a good illustration of the slowness of diffusion. It is noteworthy that the rate of diffusion is much the same for both positive and negative plates, but that the rate for a discharged is considerably less than that for a charged plate. This last difference is undoubtedly due to the formation of sulphate in the porous plugs, with the expansions indicated in the paragraph on the properties and volumes of materials. Discharge affects the rate of diffusion on the lead plate more than on the peroxide. This is in accordance with the higher rate of expansion and clogging when lead is changed to sulphate over the change from peroxide to sulphate. From what has already been said about the dependence of E.M.F. on acid strength,

Fig. 13.

it is obvious that while diffusion is proceeding there will be a corresponding change in E.M.F. Curve I., in Fig. 13, shows the rise when a positive plate, hitherto standing in 20 per cent. acid, is suddenly placed in 34 per cent.; curve II., the rise when a similar plate is taken from 20 to 58 per cent. acid (Gladstone and Hibbert, *Phil. Mag.* 1890).

In applying these diffusion and electromotive force curves to working conditions, it may be noticed that a given quantity of H_2SO_4 diffusing into very weak acid produces a much greater change in the electromotive force than if it pass into stronger acid. Thus if the acid be very weak, say, 2 per cent., a diffusion of 1 per cent. H_2SO_4 raises the E.M.F. by 0.036 volt, whereas if the acid

be 10 per cent. a diffusion of 1 per cent. raises the E.M.F. by 0.006 volt only (see Fig. 11).

The important practical questions concerning an accumulator are—its maximum rate of working, its capacity at various discharge rates, its efficiency, and its length of life. Apart from mechanical injury, all these depend on the way the cell is charged and discharged. For each type and size of cell there is a normal maximum current. Up to this limit any current may be taken, beyond it the cell may suffer. Again, it is desirable that the charge and discharge be confined between certain limits of potential difference at the terminals. Injurious excessive currents or a discharge below a potential difference of 1.8 volt

Charge and discharge.

Fig. 14.

are often accompanied by more or less disintegration. To illustrate and explain these points a connected series of observations on a given set of cells is here used, the data having been given by Ayrton, Lamb, Smith, and Woods (*Journ. Inst. Elec. Eng.* 1890). The cells employed contained three negative plates, weighing 17 lb 2 oz., two positive plates, weighing 11 lb 8 oz., and acid of 1.206 density. The plates measured 9 by 9 inches, and were intended for maximum currents of 9 amperes in charging and 10 amperes in discharging. For reasons given in the paper, it was decided to make the potential difference at terminals the governing condition of working, the limits to be 2.4 and 1.6 volt.

Fig. 14 shows a typical discharge curve; noteworthy points are:—(1) At the beginning and at the end there is a rapid fall in P.D., with an intermediate period of fairly uniform value. (2) When the P.D. reaches 1.6 volt the fall is so rapid that there is no advantage in continuing the action. When the P.D. had fallen to 1.6 volt the cell was automatically switched into a charging circuit, and with a current of 9 amperes yielded the curve in Fig. 15. Here

Fig. 15.

again there is a rapid variation in P.D. (in these cases a rise) at the beginning and end of the operation. The cells were now carried through the same cycle several times, giving almost identical values for each cycle. After some days, however, they became more and more difficult to charge, and the return on discharge was proportionately less. It became impossible to charge up to a P.D. of 2.4 volts, and finally the capacity fell away to half its first value. Examination showed that the plates were badly scaled and that some of the scales had partially connected the plates. These scales were cleared away and the experiments resumed, limiting the fall of P.D. to 1.8 volt. The difficulties then disappeared,

showing that discharge to 1.6 volt caused injury that did not arise at a limit of 1.8. Before describing the new results it will be useful to examine these two cases in the light of the theory of E.M.F. already given.

(a) *Fall in E.M.F. at beginning of discharge.*—At the moment when previous charging ceases the pores of the positive plate contain strong acid, brought there by the charging current. There is consequently a high E.M.F. But the strong acid begins to diffuse away at once and the E.M.F. falls rapidly. Even if the cell were not discharged this fall would occur, and if it were allowed to rest for thirty minutes or so the discharge would have begun with the dotted line (Fig. 14). (b) *Final rapid fall.* The pores being clogged by sulphate the plugs cannot get acid by diffusion, and when 5 per cent. is reached the fall in E.M.F. is disproportionately large (see Fig. 11). If discharge be stopped, there is an almost instantaneous diffusion inwards and a rapid rise in E.M.F. (c) *The rise in E.M.F. at beginning and end of the charging* is due to acid in the pores being strengthened, partly by diffusion, partly by formation of sulphuric acid from sulphate, and partly by electrolytic carrying of strong acid to the positive plate. The injurious results at 1.6 volt arise because then the pores contain water. The

Experiment.	Capacity and Efficiency under Various Conditions of Working.					
	Discharge.		Charge.		Efficiency.	
	Ampere Hours.	Watt Hours.	Ampere Hours.	Watt Hours.	Quantity.	Energy.
Normal cycle .	102	201.7	104.5	230.7	97.2	87.4
Restoration after 1st rest .	100	190	103.8	228.2	96.8	85.8
Ditto, after 2nd rest .	91	176.7	96.8	213.2	94.1	82.8
Ditto, after 3rd rest .	82.6	161.3	86.2	190.5	95.8	84.7
Discharge immediately after rest	56.5	110.5	86.2	190.5	65.5	58.1
	56.5	110.5	71.1	158.3	79.6	69.6
Restoration after 8 cycles .	80	156.9	83.8	184.6	95.5	85

The table shows that the efficiency in a normal cycle may be as high as 87.4 per cent.; that during a rest of sixteen days the charged accumulator is so affected that about 30 per cent. of its charge is not available, and in subsequent cycles it shows a diminished capacity and efficiency; and that by repeated charges and discharges the capacity may be partially restored and the efficiency more completely so. These changes might be due to—(a) leakage or shortcircuit, (b) some of the active material having fallen to the bottom of the cell, or (c) some change in the active materials.

Fig. 16-27.

chemistry is altered, oxide or hydrate is formed, which will partially dissolve, to be changed to sulphate when the sulphuric acid subsequently diffuses in. But formed in this way it will not appear mixed with the active masses in the electrolytic paths, but more or less alone in the pores. In this position it will more or less block the passage and isolate some of the peroxide. Further, when forming in the narrow passage its disruptive action will tend to force off the outer layers. It is evident that limitation of r.p. to 1.8 volt ought to prevent these injuries, because it prevents exhaustion of acid in the plugs. The other curves will now be easy to follow. Figs. 16 and 17 show a normal charge and discharge between the limits of 2.4 and 1.8 volt.

After the next charging the cells were allowed to rest for ten days. On discharge they showed a smaller capacity, and this was the case for several subsequent charges and discharges, though repeated chargings at last brought them back to something like the previous values. Compare Figs. 18 and 19. Two other similar series were tried; that is, rest followed by repeated and continuous work to bring the cell back to its first state (see Figs. 20, 21, 22, 23). Then another charge was followed by a rest of sixteen days. The discharge which immediately followed the rest is shown in Fig. 24, while Fig. 25 shows the next charge—a great falling-off. The cells were now taken through eight cycles of charge and discharge, and were then so far restored as to give Figs. 26 and 27. Integrating the curves, the following numbers were obtained:—

Fig. 28.

(a) is excluded by the fact that the subsequent charge is smaller, and (b) by the continued increase of capacity during the cycles that follow the rest. Hence the third hypothesis is the one which must be relied upon. The change in the active materials has already been given. The formation of lead sulphate (on both plates) explains the loss of energy shown in Fig. 24, while the fact that it is probably formed, not in the path of the regular currents, but on the wall of the grid (remote from the ordinary action), gives a probable explanation of the subsequent slow recovery. The action of the acid on the lead during rest must not be overlooked.

We have seen that capacity diminishes as the discharge rate increases; that is, the available output increases as the current diminishes. Crompton's diagram illustrating this fact is given in Fig. 28. At the higher rates the consumption of acid is too rapid, diffusion cannot maintain its strength in the pores, and the fall comes so much earlier. The resistance varies with the condition of the cell, as shown by the curves in Fig. 20. It may be unduly increased by long or narrow lugs, and especially by dirty joints between the lugs.

It is interesting to note that it increases at the end of both charge and discharge, and much more for the first than the second. Now the composition of the active materials near the end of charge is almost exactly the same as at the beginning of discharge, and at first sight there seems nothing to account for the great fall in resistance from 0.0115 to 0.004 ohm; that is, to about one-third the value. There is, however, one difference between charging and discharging—namely, that due to the strong acid near the positive, with a corresponding weaker acid near the negative electrode. The curve of conductivity for sulphuric acid shows

1 This discharge is here compared with the charge that preceded the rest; in the next line the same discharge is compared with the charge following the rest.

that both strong and weak acid have much higher resistances than the liquid usually employed in accumulators, and it is therefore reasonable to suppose that local variations in strength of acid cause the changes in resistance. That these are not due to the

discharge was due to electrolytic hydrogen and oxygen simply. He ignored the chemical action of the acid. In 1882 Gladstone and Tribe published a series of papers, showing, by analyses, that sulphate of lead was formed on both plates, the action being, before discharge,

and after discharge

These results are in harmony with Gladstone and Tribe's analyses, which showed that in every case some of the active material remained unchanged. During charge, the substances are restored to their original condition, and the equation must be reversed. The theory received abundant confirmation—from Frankland in 1883, Reynier (1884), Crova and Garbe (1885), Tcheltzow (1886), Heim and Kohlrausch (1889), Ayrton, &c., with Robertson (1890), Dolezalek (1897), and Mugdan (1899). Notwithstanding this body of evidence it has been objected to, chiefly on the ground that sulphate of lead is a white substance and is difficult to reduce to lead, whereas the substance formed in a cell is not white and is easy to reduce. But Gladstone and Tribe (and afterwards Swinburne) showed in 1883 that sulphate was easy enough to reduce when mixed with other substances like peroxide, or lead itself, which is just the condition in which it occurs in all normal working of the cells. Darrius suggests that sulphate is formed only on the negative plate, oxide of lead on the positive, and that the spongy lead is in an allotropic condition, which helps to give a higher E.M.F. This theory is contrary to the results obtained by the numerous experimenters already mentioned. Mugdan has especially shown that oxide cannot be detected on the positive plate.

Fig. 29.

constitution of the plugs is shown by the fact that, while the plugs are almost identical at end of discharge and beginning of charge, the resistance falls from 0.0055 to 0.0033 ohm.

While a current flows through a cell, heat is produced at the rate of $C^2R \times 24$ calories (water-gram-degree) per second. As a consequence the temperature tends to rise. But the change of temperature actually observed is much greater during charge, and much less during discharge, than the foregoing expression would suggest; and it is evident that, besides the heat produced according to Joule's law, there are other actions which warm the cell during charge and cool it during discharge. Messrs. Duncan and Wiegand (*loc. cit.*), who first observed the thermal changes, ascribe the chief influence to the electrochemical addition of H_2SO_4 to the liquid during charge and its removal during discharge. Fig. 30 gives some results obtained by Ayrton, Lamb, &c. This elevation of temperature (due to electrolytic strengthening of acid and local action) is a measure of the energy lost in a cycle, and ought to be minimized as much as possible.

FIG. 30.

FIG. 31.

It is doubtful if the experiment in favour of an allotropic condition of the lead can be confirmed. The body of evidence in favour of the formation of sulphate on both plates is exceedingly strong—in fact, decisive. Figs. 31 and 32 embody a complete series of chemical and physical observations; many of the preceding statements are illustrated by these curves and can be tested by their relationships. The current was stopped at the points marked A, B, C, D, to take active material for analysis; and the rise of E.M.F. in discharge, and fall in charge, during this short interval is noteworthy.

(2) Planté attributed the high charging E.M.F. to hydrogen dioxide, and similar oxygenized bodies. Gladstone and Tribe thought that occluded hydrogen and oxygen gases, though very small in quantity, might account for it. Robertson thought that the oxygenized bodies arising from persulphuric acid might raise

FIG. 32.

or lower the E.M.F. according to their exact position in a cell. If, however, these substances are added to a cell (without changing the acid strength) they do not produce a change at all comparable

The chemical theory which has been adopted in the foregoing pages is very simple. It declares that sulphate of lead is formed on both plates in discharge, the chemical action being reversed in charge.

Chemistry. Most of the other actions—associated with variations in the E.M.F. of the cell—arise from local variations in strength of acid brought about by chemical action and the electrolysis of the acid. It will contribute to a clear understanding if the chemical actions be considered under various heads:—(1) Those occurring during ordinary charge and discharge; (2) the cause of high E.M.F. at end of charge; (3) the rapid fall of E.M.F. and P.D. at end of discharge; (4) the rapid recuperation of a discharged cell when allowed to repose; (5) the effect of repose on a charged cell; and (6) the agreement of the experimental E.M.F. and that calculated by the Kelvin-Helmholtz thermodynamic equation.

(1) Planté thought that the chemical action during charge and

with that here dealt with, and there is no positive evidence that they will do what is required by the theory. The only known change which has been shown to be competent to affect the E.M.F. to this degree is the change which may locally and temporarily occur in the strength of the acid.¹

(3) There are two explanations of the rapid fall at the end of discharge. The one already given ascribes the fall to a weakening of the acid in the spongy masses. This has already been considered and need not be further elaborated. The other explanation was first given by Planté, and adopted by Gladstone and Tribe, and afterwards by Robertson. All these workers observed that, at the end of a discharge, patches or small films of peroxide of lead were formed on the surface of the lead plate. Such films speedily tend to annul the E.M.F. and bring the current to zero. Which of these two hypotheses (both representing actual facts and both competent to produce the change under consideration) contributes most to the result is a difficult question. But if a careful comparison be made of the time at which peroxide appears on the negative, with the fall of E.M.F., it will be seen that the fall begins before the films can be detected with certainty. Thus (in Fig. 32) Robertson could not be sure of peroxide on the negative at the point C, although the fall had fairly begun at that time.

(4) The explanation of the rapid recuperation after discharge is that the cause of the rapid fall has ceased and that the conditions existing before it are now re-established. If the discharge fall be ascribed to peroxide films on the negative, then on stopping the discharge the films are destroyed by local action, and the E.M.F. is restored. If the fall be due to exhaustion of acid, then stopping the current allows acid to diffuse into the pores almost instantly, and so restores the E.M.F. If the discharge has not been carried too far, this is most probably the true cause. If the potential difference is below 1.8 volt, both actions take place.

(5) As to the effect of repose on a charged cell, Gladstone and Tribe's experiments showed that peroxide of lead lying on its lead support suffered from a local action, which reduced one molecule of PbO₂ to sulphate at the same time that an atom of the grid below it was also changed to sulphate. There is thus not only a loss of the available peroxide, but a corrosion of the grid or plate. It is through this action that the supports gradually give way. On the negative plate an action arises between the finely-divided lead and the sulphuric acid, with the result that hydrogen is set free.

This involves a diminution of available spongy lead, or loss of capacity, occasionally with serious consequences. The capacity of the lead plate is reduced absolutely, of course, but its relative value is more seriously affected. In the discharge it gets sulphated too much, because the better positive keeps up the E.M.F. too long. In the succeeding charge, the positive is fully charged before the negative, and the differences between them tend to increase in each cycle.

(6) Kelvin and Helmholtz have shown that the E.M.F. of a voltaic cell can be calculated from the energy developed by the chemical action. For a dyad gram equivalent (=2 grams of hydrogen, 207 grams of lead, &c.), the equation connecting them is

$$E = \frac{H}{46000} + T \frac{dE}{dT}$$

where E is the E.M.F. in volts, H is the heat developed by a dyad equivalent of the reacting substances, T is the absolute temperature, and $\frac{dE}{dT}$ is the temperature coefficient of the E.M.F. If the E.M.F. does not change with temperature, the second term is zero. The thermal values for the various substances formed and decomposed are:—For PbO₂, 62400; for PbSO₄, 216210; for H₂SO₄, 192920; and for H₂O, 68400 calories. Writing the equation in its simplest form for strong acid, and ignoring the temperature coefficient term,

leaving a balance of 120860 calories. Dividing by 46000 gives 2.627 volts. The experimental value in strong acid, according to Gladstone and Hibbert, is 2.607 volts, a very close approximation. For other strengths of acid, the energy will be less by the quantity evolved when the acid is diluted. The dotted curve in Fig. 11 indicates the calculated E.M.F. at various points when this is taken into account. The difference between it and the continuous curve must, if the chemical theory be correct, depend on the second term in the equation. The figure shows that the observed E.M.F. is above the theoretical for all strengths from 100 down to 5 per cent. Below 5 the position is reversed. The question remains, Can the temperature coefficient be obtained? This is difficult, because the

value is so small and it is not easy to secure a good cycle of observations. Streitz has given the following values:—

E	1.9223	1.9828	2.0031	2.0084	2.0105	2.078	2.2070
$\frac{dE}{dT} \cdot 10^6$	140	228	335	285	255	130	73

These figures illustrate the difficulty of getting good determinations; it is quite improbable that cells so nearly alike as those giving 2.003 and 2.008 volts should have temperature coefficients differing by 16 per cent. Unpublished experiments by the writer give $\frac{dE}{dT} \cdot 10^6 = 350$ for acid of density 1.156. With stronger acid, a true cycle could not be obtained. Taking Streitz's value, 335 for

25 per cent. acid, the second term of the equation is $T \frac{dE}{dT} = 290 \times$

$\cdot 000335 = 0.0971$ volt. The first term gives 88800 calories = 1.9304 volt. Adding the second term, 1.9304 + 0.0971 = 2.0275 volts. The observed value is 2.030 volts (see Fig. 11 and table 2), a remarkably good agreement. This calculation and the general relation shown in Fig. 11 render it highly probable that, if the temperature coefficient were known for all strengths of acid, the result would be equally good. It is worth observing that the reversal of relationship between the observed and calculated curves, which takes place at 5 or 6 per cent., suggests that the chemistry must be on the point of altering as the acid gets weak, a conclusion which has been already arrived at on purely chemical grounds. The thermodynamical relations are thus seen to confirm very strongly the chemical and physical analyses.²

As the efficiency of accumulators is not generally higher than 75 per cent., and machines must be used to charge them, it is not directly economical to use cells alone for public supply. Yet they play an important and an increasing part in public work, because they help to maintain a constant voltage on the mains, and can be used to distribute the load on the running machinery over a much greater fraction of the day. Used in parallel with the dynamo, they quickly yield current when the load increases, and immediately begin to charge when the load diminishes, thus largely reducing the fluctuating stress on dynamo and engine for sudden variations in load. Their use is advantageous if they can be charged and discharged at a time when the steam plant would otherwise be working at an uneconomical load.

Regulation of the potential difference is managed in various ways. More cells may be thrown in as the discharge proceeds, and taken out during charge; but this method often leads to trouble, as some cells get unduly discharged, and the unity of the battery is disturbed. Sometimes the number of cells is kept fixed for supply, but the P.D. they put on the mains is reduced during charge by employing regulating cells in opposition. The working cells are then all kept in similar condition. But these methods are now being discarded. The number of cells is now fixed and the battery joined to the mains. The heaviest part of the load is shared by battery and dynamo, and after the evening's discharge the dynamo may charge the cells. But they must be charged to a higher potential difference than that kept on the mains, otherwise they cannot be said to be brought back to good condition. This may be done by disconnecting the battery and charging from a dynamo which gives the requisite higher E.M.F.; or it may be done (and this is usual) by taking the current from the mains to the battery through a "booster," that is, a dynamo arranged so that its E.M.F. is added to that of the mains. The power requisite for driving its armature may be obtained from any convenient source, but it is most usual to couple the armature to the shaft of a motor driven from the mains.

There are certain disadvantages in carrying accumulators

on tramcars. The cells add largely to the weight of the car; there is much expense in handling, owing to the substitution of charged for discharged cells every few hours; and there is a very rapid deterioration of the plates, consequent upon shaking and the heavy starting currents. For these reasons the use of cells on the cars has not generally been a commercial success, though at the present time a few lines are being run. The following table gives some particulars of two systems worked by "chloride" cells:—

Items.	Birmingham.	Paris.
Weight of battery in pounds	6048	6615
Average discharge in amperes during run	50	35
Maximum discharge during run	120-150	100-120
Length of run with one charge in miles	45	37
Speed in miles	8 to 15	8 to 15
No. of passengers carried	50	50

At Birmingham some cells have completed 20,000 car miles before renewal was necessary. Cost of renewal per car mile is approximately 1½ penny. But if the accumulators be used in the central or a sub-station, there are many advantages. In

Fig. 33.

a traction station, the load varies so rapidly that the plant is generally working at a low average load factor; and the machinery must be capable of meeting the maximum demand, while the average load does not exceed one-half of the maximum. Now accumulators will take the peaks of the load, relieving the machinery from sudden jerks, and further allowing the running plant to be reduced to that which suffices for the average load. Some idea of the significance of this may be gained from Fig. 33.

The cells are in parallel with the generator. Eight cars were running. The thick line A shows the dynamo current, varying from 115 to 150 amperes. The line current varies from 0 to 375 amperes. It is evident that engine and generator are kept fully loaded, the cells supplying the peaks and taking a charge

during the hollow. For work like this, the cells ought to have a low resistance, and it is desirable that the shunt-wound dynamo shall have a falling characteristic. Compound-wound boosters are sometimes used to help the accumulators to share the load. Fig. 34 is a diagram of the arrangement. The following data illustrate the way in which accumulators are employed in the station belonging to the Plymouth Corporation. Alternate current is used for lighting and continuous current for the tramway line. There are two combined sets; that is, engine, alternator, and tramway generator coupled on the same shaft. Other and larger alternators are in use during the "peak" of the load. In the combined sets the alternator and generator are each 100 kilowatt machines; the Belliss engine is 150 v.h.p. The engine is therefore only large enough to drive either of the machines at full load, but can run both at any combination of load not greater than 100 k.w. total. The generator gives 535 volts, and is in parallel with 260 cells of the Tudor type. The cars begin to run at 7.30 a.m. The cells and one generator are in parallel, sharing the tramway load through the day, with results very similar to those shown in Fig. 33. The alternator on the same shaft supplies the small day lighting load. When the evening lighting load comes on, the direct current generators are uncoupled, the accumulators take the tramway work, and the total engine power is available for running the fully-loaded alternators. This continues till the cars stop at 11 o'clock, by which time the lighting load has gone down again. The pressure of the cells has diminished from 520 to 475 volts. A generator is now coupled up and charges the accumulators from 11 p.m. to 2.30 or thereabouts; a booster adding from 70 to 130 volts, as may be required. The booster motor takes from 15 to 20 amperes at 530 volts, depending on the output from its dynamo. These arrangements give a well-distributed load and economical conditions of working for such machinery as is at any time running, while the cells are a stand-by for exciting plant, &c.

(W. HT.)

Acetylene, klumene or ethine, is one of the gaseous compounds of hydrogen and carbon, and on analysis is found to contain—

Carbon	92.3
Hydrogen	7.7
	100.0

The molecule is represented by the formula C_2H_2 . It is a clear, colourless gas, having a density of 0.92. When prepared by the action of water upon calcium carbide, it has a very strong and penetrating odour, but when it is thoroughly purified from sulphuretted and phosphuretted hydrogen, which are invariably present with it in minute traces, this extremely

Physical properties.

pungent odour disappears, and the pure gas has a not unpleasant ethereal smell. It can be condensed into the

Liquefaction.

liquid state by cold or by pressure, and experiments by Ansell show that if the gas be subjected to a pressure of 21.53 atmospheres at a temperature of 0° C., it is converted into the liquid state, the pressure needed increasing with the rise of temperature, and decreasing with the lowering of the temperature, until at - 82° C. it becomes liquid under ordinary atmospheric pressure. The critical point of the gas is 37° C., at which temperature a pressure of 68 atmospheres is required for liquefaction. A great future was expected from its use in the liquid state, since a cylinder fitted with the necessary reducing valves would supply the gas to light a house for a considerable period, the liquid occupying about $\frac{1}{400}$ the volume of the gas, but in the United States and on the Continent of Europe, where liquefied acetylene was made on the large scale, several fatal accidents occurred owing to its explosion under not easily explained conditions. As a result of

Explosibility of liquid acetylene.

these accidents Berthelot and Violle made a series of valuable researches upon the explosion of acetylene under various conditions. They found that if liquid acetylene in a steel bottle be heated at one point by a platinum wire raised to a red heat, the whole mass decomposes and gives rise to such tremendous pressures that no cylinder would be able to withstand them. These pressures varied from 71,000 to 100,000 lb per square inch. They, moreover, tried the effect of shock upon the liquid, and found that the repeated dropping of the cylinder from a height of nearly 20 feet upon a large steel anvil gave no explosion, but that when the cylinder was crushed under a heavy blow the impact was followed, after a short interval of time, by an explosion which was manifestly due to the fracture of the cylinder and the ignition of the escaping gas, mixed with air, from sparks caused by the breaking of the metal. A similar explosion will frequently follow the breaking in the same way of a cylinder charged with hydrogen at a high pressure. Continuing these experiments, they found that in acetylene gas under ordinary pressures the decomposition brought about in one portion of the gas, either by heat or the firing in it of a small detonator, did not spread far beyond the point at which the decomposition started, while if the acetylene was compressed to a pressure of more than 30 lb on the square inch, the decomposition travelled throughout the mass and became in reality detonation. These results showed clearly that liquefied acetylene was far too dangerous for general introduction for domestic purposes, since, although the occasions would be rare in which the requisite temperature to bring about detonation would be reached, still, if this point were attained, the results would be of a most disastrous character. The fact that several accidents had already happened accentuated the risk, and in Great Britain the storage and use of liquefied acetylene are prohibited.

When liquefied acetylene is allowed to escape from the cylinder in which it was contained into ordinary atmospheric pressure, some of the liquid assumes the gaseous condition with such rapidity as to cool the remainder below the temperature of - 90° C., and convert it into a solid snow-like mass.

Acetylene is readily soluble in water, which at normal temperature and pressure takes up a little more than its own volume of the gas, and yields a solution giving a purple-red precipitate with ammoniacal cuprous chloride and a white precipitate with silver nitrate, these precipitates consisting

of acetylides of the metals. The solubility of the gas in various liquids, as given by different observers, is—

100 Volumes of	absorb . . .	Volumes of Acetylene.
Brine	. . .	5
Water	" . . .	110
Alcohol	" . . .	600
Paraffin	" . . .	150
Carbon disulphide	" . . .	100
Fusel oil	" . . .	100
Benzene	" . . .	400
Chloroform	" . . .	400
Acetic acid	" . . .	600
Acetone	" . . .	3100

It will be seen from this table that where it is desired to collect and keep acetylene over a liquid, brine, *i.e.*, water saturated with salt, is the best for this purpose, but in practice it is found that, unless water is agitated with acetylene, or the gas bubbled through, the top layer soon gets saturated and the gas then dissolves but slowly. The great solubility of acetylene in acetone was pointed out by MM. Claude and Hess, who suggested charging acetone with the gas under pressure, a litre of acetone dissolving 360 times its own, volume of the gas under a pressure of 12 atmospheres. When the pressure is relieved the gas again escapes, and it was thought that in this way a better method of storing the gas would be provided by liquefaction. Experiment, however, has shown that acetone thus saturated under pressure shares many of the disadvantages of liquid acetylene itself.

Solution in acetone.

When acetylene was first introduced on a commercial scale grave fears were entertained as to its safety, it being represented that it had the power of combining with certain metals, more especially copper and silver, to form acetylides of a highly explosive character, and that even with coal gas, which contains less than 1 per cent., such copper compounds had been known to be formed in cases where the gas distributing mains were composed of copper, and that accidents had happened from this cause. It was therefore predicted that the introduction of acetylene on a large scale would be followed by numerous accidents unless copper and its alloys were rigidly excluded from contact with the gas. These fears have, however, fortunately proved to be unfounded, and ordinary gas fittings can be used with perfect safety with this gas.

Explosive compounds with metals.

Acetylene was at one time supposed to be a highly poisonous gas, the researches of Bistrow and Liebreich having apparently shown that it acts upon the blood in the same way as carbon monoxide to form a stable compound. Very extensive experiments, however, made by Drs Grehant, Brociner, Malooz, Crismer, and others, all conclusively show that acetylene is much less toxic than carbon monoxide and indeed than coal gas.

Poisonous properties.

Acetylene has the property of inflaming spontaneously when brought in contact with chlorine. If a few pieces of carbide be dropped into saturated chlorine water the bubbles of gas take fire as they reach the surface, and if a jet of acetylene be passed up into a bottle of chlorine it takes fire and burns with a heavy red flame, depositing its carbon in the form of soot. If chlorine be bubbled up into a jar of acetylene standing over water, a violent explosion, attended with a flash of intense light and the deposition of carbon, at once takes place. When the gas is kept in a small glass holder exposed to direct sunlight, the surface of the glass soon becomes dimmed, and Bone has shown that when exposed for some time to the sun's rays it undergoes certain polymerization changes which lead to the deposition of a film of heavy hydrocarbons on the surface of the tube.

Chemical actions.

It has also been observed by Cailletet and later by Villard that when allowed to stand in the presence of water at a low temperature a solid hydrate is formed. Acetylene is readily decomposed by heat, polymerizing under its influence to form an enormous number of organic compounds; indeed the gas, which can itself be directly prepared from its constituents, carbon and hydrogen, under the influence of the electric arc, can be made the starting-point for the construction of an enormous number of different organic compounds of a complex character. In contact with nascent hydrogen it builds up ethylene; ethylene acted upon by sulphuric acid yields sulphovinic acid; this can again be decomposed in the presence of water to yield alcohol, and it has also been proposed to manufacture sugar from this remarkable body. Picric acid can also be obtained from it by first treating acetylene with sulphuric acid, converting the product into phenol by solution in potash, and then treating the phenol with fuming nitric acid.

Detonation. Acetylene is one of those bodies the formation of which is attended with the disappearance of heat, and it is for this reason termed an "endothermic" compound, in contra-distinction to those bodies which evolve heat in their formation, and which are called "exothermic." Such endothermic bodies are nearly always found to show considerable violence in their decomposition as the heat of formation stored up within them is then liberated as sensible heat, and it is undoubtedly this property of acetylene gas which leads to its easy detonation by either heat or a shock from an explosion of fulminating mercury when in contact with it under pressure. The observation that acetylene can be resolved into its constituents by detonation is due to Berthelot, who started an explosive wave in it by firing a charge of 0.1 gram of mercury fulminate. It has since been shown, however, that unless the gas is at a pressure of more than two atmospheres this wave soon dies out, and the decomposition is only propagated a few inches from the detonator. Heated in contact with air to a temperature of 480°

Ignition point. C. acetylene ignites and burns with a flame, the appearance of which varies with the way in which it is brought in contact with the air. With the gas in excess a heavy lurid flame emitting dense volumes of smoke results, whilst if it be driven out in a sufficiently thin sheet, it burns with a flame of intense brilliancy and almost perfect whiteness, by the light of which colours can be judged as well as they can by daylight. Having its ignition point below that of ordinary gas, it can be ignited by any red-hot carbonaceous matter, such as the brightly glowing end of a cigar. For its complete combustion a volume of acetylene needs approximately twelve volumes of air, forming as products of combustion carbon dioxide and water vapour. When, however, the air is present in much smaller ratio the combustion is incomplete, and carbon, carbon monoxide, carbon dioxide, hydrogen, and water vapour are produced. This is well shown by taking a cylinder one-half full of acetylene and one-half of air; on applying a light to the mixture a lurid flame runs down the cylinder and a cloud of soot is thrown up, the cylinder also being thickly coated with it, and often containing a ball of carbon. If now, after a few moments' interval to allow some air to diffuse into the cylinder, a taper again be applied, an explosion takes place, due to a mixture of carbon monoxide and air. It is probable that when a flame is smoking badly, distinct traces of carbon monoxide are being produced, but when an acetylene flame burns properly the products are as harmless as those of coal gas, and, light for light, less in amount. Mixed with air, like every other combustible

Combustion. gas, acetylene forms an explosive mixture. Clowes has shown that it has a wider range of explosive proportions when mixed with air than any of the other combustible gases, the limiting percentages being as follows:—

Explosive mixtures.

Acetylene	3 to 82
Hydrogen	5 to 72
Carbon monoxide	13 to 75
Ethylene	4 to 22
Methane	5 to 13

The methods which can be and have been employed from time to time for the formation of acetylene in small quantities are exceedingly numerous. Before the commercial production of calcium carbide made it one of the most easily obtainable gases, the processes which were most largely adopted for its preparation in laboratories were:—first, the decomposition of ethylene bromide by dropping it slowly into a boiling solution of alcoholic potash, and purifying the evolved gas from the volatile bromethylene by washing it through a second flask containing a boiling solution of alcoholic potash, or by passing it over moderately heated soda lime; and, second, the more ordinarily adopted process of passing the products of incomplete combustion from a Bunsen burner, the flame of which had struck back, through an ammoniacal solution of cuprous chloride, when the red acetylide of copper was produced. This on being washed and decomposed with hydrochloric acid yielded a stream of acetylene gas. This second method of production has the great drawback that, unless proper precautions are taken to purify the gas obtained from the copper acetylide, it is always contaminated with certain chlorine derivatives of acetylene. Edmund Davy first made acetylene in 1836 from a compound produced during the manufacture of potassium from potassium tartrate and charcoal, which under certain conditions yielded a black compound decomposed by water with considerable violence and the evolution of acetylene. This compound was afterwards fully investigated by Berzelius, who showed it to be carbide of potassium. He also made the corresponding sodium compound and showed that it evolved the same gas, whilst in 1862 Wöhler first made carbide of calcium, and found that water decomposed it into lime and acetylene. It was not, however, until 1892 that the almost simultaneous discovery was made by Willson in America and Moissan in France that if lime and carbon be fused together at the temperature of the electric furnace, the lime is reduced to calcium, which unites with the excess of carbon present to form calcium carbide. The cheap production of this material and the easy liberation by its aid of acetylene at once gave the gas a position of commercial importance. In the manufacture of calcium carbide in the electric furnace, lime and hard metallurgical coke of the highest possible degree of purity are employed. A good working mixture of these materials may be taken as being 100 parts by weight of lime with 68 parts by weight of carbonaceous material. About 1.8 lb of this is used up for each pound of carbide produced. The two principal processes utilized in making calcium carbide by electrical power are the ingot process and the tapping process. In the former, the coke and lime are finely ground and carefully mixed in the right proportions to suit the chemical actions involved. The arc is struck in a crucible into which the powdered mixture is allowed to flow, partially filling it. An ingot gradually builds up from the bottom of the crucible, the carbon electrode being raised from time to time automatically or by hand to suit the diminution of resistance due to the shortening of the arc by the rising ingot. The

Methods of production.

Manufacture of calcium carbide.

crucible is of metal and considerably larger than the ingot, the latter being surrounded by a mass of unreduced material which protects the crucible from the intense heat. When the ingot has been made and the crucible is full, the latter is withdrawn and another substituted. The process is not continuous, but a change of crucibles only takes two or three minutes under the best conditions, and only occurs every ten or fifteen hours. The essence of this process is that the coke and lime are only heated to the point of combination, and are not "boiled" after being formed. It is found that the ingot

"Ingot" carbide.

of calcium carbide formed in the furnace, although itself consisting of pure crystalline calcium carbide, is nearly always surrounded by a crust which contains a certain proportion of imperfectly converted constituents, and therefore gives a lower yield of acetylene than the carbide itself. In breaking up and sending out the carbide for commercial work, packed in air-tight drums, the worst of the crust is as far as possible picked out and rejected. A statement of the amount made per kilowatt hour may be misleading, since a certain amount of loss is of necessity entailed during this process. For instance, in practical working it has been found that a furnace return of 0.504 lb per kilowatt hour is brought down to 0.406 lb per kilowatt hour when the material has been broken up, sorted, and packed in air-tight drums. In the tapping process a fixed crucible

"Run" carbide.

is used, lined with carbon, the electrode is nearly as big as the crucible, and a much higher current density is used. Fine grinding is unnecessary, as combination probably only takes place after fusion of the raw materials which mix more or less as liquids. The carbide is heated to complete liquefaction and tapped at short intervals. There is no unreduced material, and the process is considerably simplified, while less expensive plant is required. The run carbide, however, is never so rich as the ingot carbide, since an excess of lime is nearly always used in the mixture to act as a flux, and this remaining in the carbide lowers its gas-yielding power. Many attempts have been made to produce the substance without electricity, but have met with no commercial success.

Carbide of calcium, as formed in the electric furnace, is a beautiful crystalline semi-metallic solid, having a density of 2.22, and showing a fracture which is often shot with iridescent colours. It can be kept unaltered in dry air, but the smallest trace of moisture in the atmosphere leads to the evolution of minute quantities of acetylene and gives it a distinctive odour. It is infusible at temperatures up to 2000° C., but can be fused in the electric arc. When heated to a temperature of 245° C. in a stream of chlorine gas it becomes incandescent, forming calcium chloride and liberating carbon, and it can also be made to burn in oxygen at a dull red heat, leaving behind a residue of calcium carbonate. Under the same conditions it becomes incandescent in the vapour of sulphur, yielding calcium sulphide and carbon disulphide; the vapour of phosphorus will also unite with it at a red heat. It is a compound of

Calcium	:	:	:	:	:	62.5 per cent.
Carbon	:	:	:	:	:	37.5
						100.0

Acted upon by water it is at once decomposed, yielding acetylene and calcium hydrate. Pure crystalline calcium carbide yields 5.8 cubic feet of acetylene per pound at ordinary temperatures, but the carbide as sold commercially, being a mixture of the pure crystalline material with the crust

The yield from calcium carbide.

which in the electric furnace surrounds the ingot, yields an average of 5 cubic feet of gas per pound under proper conditions of generation. The volume of gas obtained, however, depends very largely upon the form of apparatus used, and while some will give the full 5 cubic feet, other apparatus will only yield, with the same carbide, 3½ feet. The purity of the carbide entirely depends on the purity of the material used in its manufacture, and before this fact had been fully grasped by manufacturers, and only the purest material obtainable employed, it contained notable quantities of compounds which during its decomposition by water yielded a somewhat high proportion of impurities in the acetylene generated from it. Although at the present time a marvellous improvement has taken place all round in the quality of the carbide produced, the acetylene nearly always contains minute traces of hydrogen, ammonia, sulphuretted hydrogen, phosphuretted hydrogen, siliciuretted hydrogen, nitrogen, and oxygen, and sometimes minute traces of carbon monoxide and dioxide. The formation of hydrogen is caused by small traces of metallic calcium occasionally found free in the carbide, and cases have been known where this was present in such quantities that the evolved gas contained nearly 20 per cent. of hydrogen. This takes place when in the manufacture of the carbide the material is kept too long in contact with the arc, since this overheating causes the dissociation of some of the calcium carbide and the solution of metallic calcium in the remainder. The presence of free hydrogen is nearly always accompanied by siliciuretted hydrogen formed by the combination of the nascent hydrogen with the silicon in the carbide. The ammonia found in the acetylene is due to the presence of magnesium nitride in the carbide. This is formed by the metallic magnesium in the molten condition taking up nitrogen from the air. On decomposition by water ammonia is produced by the action of steam or of nascent hydrogen on the nitride, the quantity formed depending very largely upon the temperature at which the carbide is decomposed. The formation of nitrides by actions of this kind and their easy conversion into ammonia, will probably at some no very distant date prove a useful method for fixing the nitrogen of the atmosphere and rendering it available for manurial purposes, although it could never compete in price with the ammonia formed in the destructive distillation of coal for coal gas. Sulphuretted hydrogen, which is invariably present in commercial acetylene, is formed by the decomposition of aluminium sulphide. Murlet has shown that aluminium sulphide, zinc sulphide, and cadmium sulphide are the only sulphur compounds which can resist the heat of the electric furnace without decomposition or volatilization, and of these aluminium sulphide is the only one which is decomposed by water with the evolution of sulphuretted hydrogen. In the early samples of carbide this compound used to be present in considerable quantity, but now rarely more than 1/10 per cent. is to be found. Phosphuretted hydrogen, one of the most important impurities, which has been blamed for the haze formed by the combustion of acetylene under certain conditions, is produced by the action of water upon traces of calcium phosphide found in carbide. Although at first it was no uncommon thing to find a half per cent. of phosphuretted hydrogen present in the acetylene, this has now been so reduced by the use of pure materials that the average quantity is rarely above 0.15 per cent., and it is often not one-fifth of that amount.

In the generation of acetylene from calcium carbide and water, all that has to be done is to bring these two compounds into contact, when they mutually react upon each other with the

Generation of acetylene from carbide.

formation of lime and acetylene, while, if there be sufficient water present, the lime combines with it to form calcium hydrate.

Every operation, no matter how simple it appears at first sight, is capable of being performed in several ways, and decomposition of the carbide by water may be brought about either by bringing the water slowly into contact with an excess of carbide, or by dropping the carbide into an excess of water, and these two main operations again may be varied by innumerable ingenious devices by which the rapidity of the contact may be modified or even eventually stopped. The result is that although the forms of apparatus utilized for this purpose are all based on the one fundamental principle of bringing about the contact of the carbide with the water which is to enter into double decomposition with it, they have been multiplied in number to a very large extent by the methods employed in order to ensure control in working, and to get away from the dangers and inconveniences which are inseparable from a too rapid generation.

In attempting to classify acetylene generators some authorities have divided them into as many as six different classes, but this is hardly necessary, as they may be divided into two main classes:—first, those in which water is brought in contact with the carbide, the carbide being in excess during the first portion of the operation; and, second, those in which the carbide is thrown into water, the amount of water present being always in excess. The first class may again be subdivided into generators in which the water rises in contact with the carbide, in which it drips upon the carbide, and in which a vessel full of carbide is lowered into water, and again withdrawn as generation becomes excessive. Some of these generators are constructed to make the gas only as fast as it is consumed at the burner, with the object of saving the expense and room which would be involved by a storage-holder. Generators with devices for regulating and stopping at will the action going on are generally termed "automatic." Another set merely aims at developing the gas from the carbide and putting it into a storage-holder with as little loss as possible, and these are termed "non-automatic." The points to be attained in a good generator are:—

1. Low temperature of generation.
2. Complete decomposition of the carbide.
3. Maximum evolution of the gas.
4. Low pressure in every part of the apparatus.
5. Ease in charging and removal of residues.
6. Removal of all air from the apparatus before generation of the gas.

When carbide is acted upon by water considerable heat is evolved; indeed, the action develops about one-twentieth of the heat evolved by the combustion of carbon. As, however, the temperature developed is a function of the time needed to complete the action, the degree of heat attained varies with every form of generator, and while the water in one form may never reach the boiling-point, the carbide in another may become red-hot and give a temperature of over 800° C. Heating in a generator is not only a source of danger, but also lessens the yield of gas and deteriorates its quality. The best forms of generator are either those in which water rises slowly in contact with the carbide, or the second main division in which the carbide falls into excess of water.

It is clear that acetylene, if it is to be used on a large scale as a domestic illuminant, must undergo such pro-

cesses of purification as will render it harmless and innocuous to health and property, and the sooner it is recognized as absolutely essential to purify acetylene before consuming it the sooner will the gas acquire the popularity it deserves. The only one of the impurities which offers any difficulty in removal is the phosphuretted hydrogen. There are three substances which can be relied on more or less to remove this compound, and the gas to be purified may be passed either through acid copper salts, through bleaching powder, or through chromic acid. In experiments with these various bodies it is found that they are all of them effective in also ridding the acetylene of the ammonia and sulphuretted hydrogen, provided only that the surface area presented to the gas is sufficiently large. The method of washing the gas with acid solutions of copper has been patented by Herr A. Frank of Charlottenburg, who finds that a concentrated solution of cuprous chloride in an acid, the liquid being made into a paste with kieselguhr, is the most effective. Where the production of acetylene is going on on a small scale this method of purification is undoubtedly the most convenient one, as the acid present absorbs the ammonia, and the copper salt converts the phosphuretted and sulphuretted hydrogen into phosphates and sulphides. The vessel, however, which contains this mixture has to be of earthenware, porcelain, or enamelled iron on account of the free acid present; the gas must be washed after purification to remove traces of hydrochloric acid, and care must be taken to prevent the complete neutralization of the acid by the ammonia present in the gas. The second process is one patented by Dr Ullmann of Geneva, who utilizes chromic acid to oxidize the phosphuretted and sulphuretted hydrogen and absorb the ammonia. The third process owes its inception to Lunge, who recommends the use of bleaching powder. Dr Wolff has found that when this is used on the large scale there is a risk of the ammonia present in the acetylene forming traces of chloride of nitrogen in the purifying boxes, and as this is a compound which detonates with considerable local force, it occasionally gives rise to explosions in the purifying apparatus. If, however, the gas be first passed through a scrubber so as to wash out the ammonia this danger is avoided. Dr Wolff employs purifiers in which the gas is washed with water containing calcium chloride, and then passed through bleaching powder solution or other oxidizing material.

When acetylene is burnt from a 000 union jet burner, at all ordinary pressures a smoky flame is obtained, but on the pressure being increased to 4 inches a magnificent flame results, free from smoke, and developing an illuminating value of 240 candles per 5 cubic feet of gas consumed. Slightly higher values have been obtained, but 240 may be taken as the average value under these conditions. When acetylene was first introduced as a commercial illuminant in England, very small union jet nipples were utilized for its consumption, but after burning for a short time these nipples began to carbonize, the flame became distorted, and then smoking occurred through the formation of a heavy deposit of soot. While these troubles were being experienced in England, attempts had been made in America to use acetylene diluted with a certain proportion of air which permitted it to be burnt in ordinary flat flame nipples; but the danger of such admixture being recognized, nipples of the same class as those used in England were employed, and the same troubles ensued. In France, single jets made of glass were first employed, and then Risener, Luchaire, Ragot, and others, made burners in which two jets of acetylene, coming from two tubes placed some little distance apart, impinged and splayed each other

Generators.

out into a butterfly flame. Soon afterwards, Billwiller introduced the idea of sucking air into the flame at or just below the burner tip, and at this juncture the Naphey or Dolan burner was introduced in America, the principle employed being to use two small and widely separated jets instead of the two openings of the union jet burner, and to make each a minute Bunsen, the acetylene dragging in from the base of the nipple enough air to surround and protect it while burning from contact with the steatite. This class of burner has been very successful, and its introduction, together with the realization of the importance of purifying the gas before combustion, has removed perhaps the most important obstacle to the use of this beautiful illuminant.

(V. B. L.)

Achill Island, off the west coast of Ireland, part of the county of Mayo. Now under the control of the Congested Districts Board, who have made efforts to improve the condition of the people. There is now a station at Achill Sound, which is crossed by a swivel bridge opened in 1888. Population, 4677.

Achin (Dutch *Atjeh*) and its dependencies form a government of Northern Sumatra, extending from 2° 53' N. on the W. coast to 4° 32' N. on the E. coast. The area of Achin is estimated at 20,520 square miles. Since 1874 the valley of the Achin river has been subjugated by the Dutch. The restriction of export and import to Achin (1888) and further regulation of the ports (1892), the death of the traitor Tuku Umar, and the successful expeditions of General van Heutsz (1898-99) on both coasts and in the valley, have broken resistance and firmly established Dutch government. A scheme to unite the coasts by a railway is under consideration. The administrative divisions are as follows—1. Great Achin (the nine districts within and beyond the military posts) with Poeloe Wai (isle); 2. dependencies (west coast, with the island of Simalu [Babi or Hog], north coast, east coast, and the southern settlements of Great Achin). Under the military and civil chief is a resident (for the regulation of shipping and Achin affairs), and under him again assistant-residents for the dependencies. Geographical knowledge of the Achin valley, river, and coast has been considerably advanced since 1874. In its upper part, near Selimun, the valley is 3 miles broad, the river having a breadth of 99 feet and a depth of 1½ feet; but in its lower course, north of its junction with the Krung Daru, the valley broadens to 12½ miles. The marshy soil is covered by rice-fields, and on higher ground by *kampongs* full of trees. The river at its mouth is 327 feet broad and 20-33 feet deep, but before it lies a sandbank covered at low water by a depth of only 4 feet. The coasts are low and the rivers insignificant, rising in the coast ranges and flowing through the coast states (the chief of which are Pedir, Gighen, and Samalanga on the N., Edi, Perlak, and Langsar on the E., Kluwah, Rigas, and Melabuh on the W.). The chief ports are Olehleh, the port of Kotaraja or Achin (formerly Kraton, now the seat of the Dutch Government), Segli on the N., Edi on the E., and Analabu or Melabuh on the W., all visited by steamers of the Royal Packet Company.

The relief of the soil of Achin is imperfectly understood. With regard to the west coast, Resident van Langen has spoken of the Barisan and other parallel ranges which are characteristic of the island of Sumatra, and a

geological description of a small portion of the same coast has been given by the mining engineer Renaud, but the interior, possibly a continuation of the Batta plateau, is unexplored. The population of Achin in 1898 was estimated at 535,432, of whom 328 were Europeans, 3933 Chinese, 30 Arabs, and 372 other foreign Asiatics. The natives of this commercial state are of very mixed origin (Hindu, Klings, Malay, Arab). They live in *kampongs*, collections of houses and gardens, which combine to form *mukims* or districts, which again combine to form *sagis*, of which there are three. The chief of a *mukim* is called an *imeum*, of a *sagi* a *panglima sagi*. The people of the highlands (*orang tunong*) differ in many respects from those of the lowlands (*orang baroh*). The means of subsistence are furnished by the culture of rice, betel (pinang), tobacco, and pepper, but agriculture and stock-raising both declined during the war. The following industries are of some importance—gold-working, weapon-making, silk-weaving, the making of pottery, fishing and coasting trade. The value of the exports (chiefly pepper) has of late years been about £58,000, of the imports from £165,000 to £250,000.

(C. M. K.)

Achinsk, a district town of Russia, East Siberia, government of Yeniseisk, 110 miles by rail W. of Krasnoyarsk, and on the Chulym river. It was founded in 1642, and remained quite insignificant till lately, when steamers began to ply on the Chulym to the gold mines. There are tanneries and soap and candle works. Population (1860), 2501; (1897), 6714.

Achromatic Objectives.—The general equation for two lenses in contact and of negligible thicknesses is,

$$P = A(n - 1) + B(n' - 1),$$

where P is the power of the combined system, or the reciprocal of its focal length, A and B are the sums of the reciprocals of the radii of curvatures of the first and second lenses respectively, and n and n' are the indices of refraction of the materials of which these two lenses are made. It is obvious that in general the value of P varies with the refrangibility of light, i.e., with its wave-length. The mathematical condition which must obtain in order that the power shall be invariable is that the derivative of this equation shall vanish, or

$$\frac{dP}{dn} = 0 = A + B \frac{dn'}{dn}.$$

Lenses, whether binary or multiple, subject to this condition and employed for the formation of real images are called achromatic objectives. These two equations would serve to determine the values of A and B, when P is assumed, and thus completely solve the problem in its elementary form, were it not unfortunately true that the value of the coefficient $\frac{dn'}{dn}$ (called the dispersive ratio), for all practicable materials is far from constant throughout the range of wave-lengths which are involved in optical images. For example, for the kinds of glass most generally employed for large telescopes, this quantity varies from 1.80 in the extreme red to 2.20 in the extreme violet. The method of fixing upon the most advantageous value to substitute in the second equation was not obvious to the earlier opticians, even to those who produced some of the finest telescopes now in use; but it is easily demonstrated that the value should be that which obtains for light of

maximum efficiency for the purpose to which it is to be applied. Thus, for visual use the value of $\frac{dn'}{dn}$ corresponding to a wave-length of about 5600 is best, while for photography with ordinary sensitive plates that for a wave-length of about 4300, a materially larger value, should be substituted.

The variability in the dispersive ratio for different regions of the spectrum gives rise to an imperfection in achromatic combinations, which, immaterial in small lenses, becomes of serious consequence in large telescopes and in spectroscopes. In astronomical telescopes the defect appears as a fringe of colour, properly violet, about bright objects; it also renders such instruments quite unavailable for photography. In spectroscopes it necessitates a continuous change in adjustment from one end of the spectrum to the other. As it constitutes the gravest error in the modern telescope, many efforts have been made during more than a century for its elimination. A review of the success attained necessitates a consideration of other defects to which objectives are subject. These may be tabulated as follows:—

1. Chromatic differences of focal length, or secondary colour.
2. Chromatic differences of spherical aberration.
3. Chromatic differences of magnification.
4. Zonal differences of magnification.
5. Images by reflections which illuminate the field.

All of these are inherent in refracting objectives, and no maker, however skilful, is able wholly to eliminate them. The highest success in designing an objective is only attainable by a due regard to the relative importance of these errors, and an adjustment of them to the purpose to which the instrument is to be applied.

In the table of errors the first is that already considered and shown to be dependent on the optical properties of the materials employed; 3 is not distinguishable from this except in cases where the members of the optical system are separated, as in microscopes and camera objectives, and in some forms of telescope; 5, known as "ghosts" to opticians, is fixed as to number, but the positions of the images can be advantageously restricted. To explain the errors 2 and 4, especially important for our present purpose, another term must be first defined.

When a single lens is used for forming an image of a remote object, it is found that the power of the lens always increases continuously with the distance of the portion used from the axis; in other words, the focal lengths of the concentric zones, into which the lens may be regarded as divided, continuously decrease with their diameters. This phenomenon, whose magnitude depends upon the shape as well as upon the power of the lens, is called spherical aberration. It is easy to see that it would be possible to combine a positive lens of such a shape as to yield a small degree of spherical aberration with a properly formed negative lens, even numerically less in power, so as to give a combination free from aberration for light of a chosen refrangibility. An achromatic combination which meets this condition for remote sources of light is a telescope objective. If free from spherical aberration for yellow light it will still possess aberration for light of less refrangibility, while for shorter wave-lengths it will be over-corrected, or have negative aberration. This property, given as 2 in the table, is quite negligible in telescope objectives constructed of ordinary materials, but in microscopic objectives of high efficiency it becomes by far the most serious error.

The error 4 is illustrated in the preceding paragraph as accompanying spherical aberration. In a combined system it may exist independently of such aberration,

and it is especially to be avoided in all instruments in which precision of images at even moderate distances from the axis is desired, such as meridian instruments, heliometers, and in all photographic objectives. The analytical condition for this end is that the sine of the angle of deviation of the light of each zone, in the production of an axial image, shall bear a constant ratio to the diameter of the zone.

The extent of secondary colour error (1 of the table) is pretty nearly independent of the kinds of glass employed, provided that only silicic acid, soda, potash, lime, or oxide of lead enter into the composition of the materials. Fraunhofer seems to have experimented with boracic acid as a partial substitute for silica, but without satisfactory results. The experiments of the eminent Jena glass-makers with phosphate crowns and borate flints are optically highly successful, but unfortunately none of these materials is permanent. Recent experiments by the same makers with a very light flint and a dense crown are more promising, but the chromatic differences of spherical aberration are so great, even when the ratio of focal length to aperture is unduly increased over the customary value, that the gain for astronomical use is problematical. Doubtless the Jena potash crown and a boro-silicate flint make the best binary combination for visual telescopes, although the crown has the great disadvantage of being strongly hygroscopic. A triple combination of ordinary crown and flint with a boro-silicate flint has been used with success, but the necessary increase of focal length, together with the fact that the number of harmful reflections is increased from six, the number of the binary lens, to fifteen, renders the advantage in telescopes of large size questionable. A quadruple cemented combination of ordinary crown and flint with potash crown and boro-silicate flint, is practically perfect for small telescopes, and can be unhesitatingly recommended for spectroscopic use.

In microscope objectives the unrecognized error of chromatic differences of spherical aberration rendered all advance in the improvement of that important aid to scientific research nearly stationary for a third of a century, until Abbe made the brilliant discovery that it is possible to eliminate it by a proper separation of the parts of the optical system. Very summarily stated, his method is this—a front, often quite complex in construction, strongly under-corrected for both colour and sphericity, is increased in power by a back system over-corrected in both particulars to the requisite degree. The character of the image produced is found to vary greatly with the separation of the two systems, so that with successive trials a solution may ultimately be discovered in which the defect in question disappears. It is true that this process necessarily introduces the error 3 in a very marked degree, but this may be practically compensated by employing an ocular with equivalent errors of an opposite sign.

The proper method of designing an objective, after finding the optical constants of the materials which are to be employed, is to deduce the values of A and B from the equations above, and then, assuming a ratio for the two radii of the first lens which experience has shown to approximate to the form desired, find by successive trigonometrical computations (not neglecting thicknesses and separations) the remaining constants of construction which adjust the various errors to the best values for the purposes to which the objective is to be applied. (c. s. H.)

Acid and Alkali Manufacture.—We comprise under this heading the manufacture of the three great mineral acids (sulphuric, hydrochloric, and nitric), and that of the carbonate and hydrate of sodium, from which, however, the manufacture of chlorine and its com-

pounds cannot be entirely separated. The manufacture of acids and alkali, understood as above, is by far the most important of inorganic chemical industries, and occupies the great bulk of the capital and labour employed in that direction. It is, at the same time, the indispensable groundwork of all organic chemical industries, as well as of glass-making, paper-making, and many other branches of human activity. We can here give merely an outline of the progress made in these manufactures during the last twenty-five years, and of their actual state and their prospects for the immediate future.

Sulphuric Acid (comp. *Ency. Brit.* vol. xxii. p. 636).—Nearly all sulphuric acid, in its various states of dilution with water, is still made by the old "lead-chamber process," while all sulphuric anhydride, SO_3 , together with its solutions in sulphuric acid, known as fuming or Nordhausen oil of vitriol, is now made by the "contact process." The last-named process is probably destined to supersede the lead-chamber process in the near future for the manufacture of concentrated sulphuric acid, *i.e.*, acid containing 92 per cent. H_2SO_4 and upwards. Acid, however, of less concentration (80 per cent. and below) has so far been made more advantageously by the old process, and this state of affairs will probably continue, at least until the respective patents have run out, especially since the large capital sunk in lead chambers is necessarily looking for some return, and is not likely to be abandoned without a determined struggle.

The first step is common to both processes, *viz.*, the manufacture of more or less dilute sulphur dioxide from elementary sulphur, or from such sulphur compounds as readily act upon atmospheric oxygen with formation of sulphur dioxide (sulphurous anhydride, SO_2). The elementary sulphur is generally native brimstone, though in exceptional cases use is made of the sulphur recovered as a by-product in the manufacture of coal-gas, or from alkali waste, &c. The great bulk of the brimstone of commerce still comes from Sicily (comp. *Ency. Brit.* vol. xxii. p. 634); in comparison with this source of supply, the brimstone obtained in Japan and a few other localities plays but a very secondary part, and the great deposits of sulphur stated to exist in other localities, such as the southern states of North America, Mexico, Daghestan, &c., have not as yet been made available to any considerable extent. The production of sulphur dioxide from elementary sulphur seems a very simple operation; yet room has been left for many improvements made during the last decades by the introduction of continuously working burners, and by the utilization of the heat generated during the process. In most localities brimstone is too expensive an agent for the manufacture of sulphuric acid; in England it is used to a very limited extent for the manufacture of acid free from arsenic, and to a much larger extent in North America and Japan, but hardly at all in other countries. The great bulk of sulphuric acid is made by "roasting" metallic sulphides, principally *pyrites* and *blende*. *Pyrites* in the pure state, FeS_2 , occurs in many countries in large quantities; most of that burned in the United Kingdom comes from Spain, and contains a small quantity of copper which is extracted from the residues ("cinders"). Spanish *pyrites* is also used in Germany, France, and America, together with the *pyrites* mined in those countries. Good *pyrites* contains from 48 to 50 per cent., and exceptionally good, 52 per cent. of sulphur, of which from 1 to 4 per cent. or upwards is left in the cinders. *Blende*, the most important of zinc ores, contains only about half as much sulphur, which is, moreover, burned off with much more difficulty; but as this has to be done in any case, in order to prepare the ore for the extraction of the metal, and as suitable apparatus

has been constructed for the purpose, very large quantities of sulphuric acid are now made from *blende*, especially in Germany and Belgium, and to some extent also in England and America.

The roasting of *pyrites* always takes place without using any extraneous fuel, the heat given off by the oxidation of the sulphur and the iron being quite sufficient to carry on the process. If the ore is in pieces of the size of a walnut or upwards, it is roasted in plain "kilns" or "burners," provided with a grating of suitable construction for the removal of the cinders, with a side door in the upper part for charging in the fresh ore on the top of the partially burned ore, and with an arch-shaped roof, from which the burner-gas is carried away in a flue common to a whole set of kilns. The latter are always set in a row of twelve or more, and are one after another charged once or twice a day at appropriate intervals, so that a regular evolution of gas takes place all the day round. By employing suitable precautions, a gas of approximately uniform composition is obtained, containing from 6 to 8 per cent. SO_2 , with a little SO_3 , and about 12 per cent. of oxygen, which is more than sufficient for converting later all the SO_2 into SO_3 or H_2SO_4 . The burning of "small" or "dust" was formerly considered much more difficult and incomplete than that of pieces, but this difficulty has been entirely overcome in various ways, principally by the "shelf-burner," originally constructed by Maletra, and by mechanical burners, which were formerly almost entirely confined to America, where the saving of labour is a primary consideration. Quite recently the Herreshoff mechanical burner (developed from a burner constructed many years ago by M'Dougal Bros., of Liverpool) is making its way also in Europe. The roasting of *blende* is nothing like so easy as that of *pyrites*, since the heat developed by the oxidation of the zinc sulphide itself is not sufficient for carrying on the process, and external heat must be applied. It is now usually performed by a series of muffles, superposed one over another, so that the whole forms a kind of shelf-burner, with internally heated shelves (the "Rhemania" furnace). This operation is both more costly and more delicate than the roasting of *pyrites*, but it is now perfectly well understood, and gas is obtained from *blende* furnaces hardly inferior in quality to that yielded by *pyrites* kilns. In America, and quite exceptionally also in Europe, mechanical furnaces are used for the roasting of *blende*.

Both kinds of gas, when issuing from the burner, hold in mechanical suspension a considerable quantity of "flue-dust," which must be removed as far as is practicable before the gas is subjected to further treatment. Flue-dust contains principally ferric oxide, zinc oxide, arsenious and sulphuric acids, and small quantities of the various metals occurring in the raw ore. All the thallium and selenium on the market is obtained from this source. Sometimes the burner-gas is employed directly for the sake of the SO_2 which it contains, principally in the manufacture of "sulphite cellulose" from wood. If it is to be utilized for the manufacture of sulphuric acid, the practice up to the present has been, with few exceptions, to carry it into "lead chambers" (vitriol chambers), which are immense receptacles constructed of sheet-lead burned together without any solder and suitably supported outside by wooden or iron framework. In these the sulphur dioxide acts upon the oxygen contained in the same gas, and upon water introduced as a spray or in the shape of steam, and the reaction $\text{SO}_2 + \text{O} + \text{H}_2\text{O} = \text{H}_2\text{SO}_4$ is brought about. As, however, this reaction of its own accord takes place only to a very small extent, an "oxygen carrier" is always introduced in the shape of the vapours of nitric acid or the lower oxides of nitrogen. By the play of

reactions induced in this way, practically the whole of the SO_2 is ultimately converted into sulphuric acid, and at the same time the nitrogen oxides are always recovered with comparatively very slight losses and made to serve over again.

The reactions taking place in the vitriol chambers are very complicated, and have been explained in many different ways. The view now accepted by most chemists is that developed by Lunge, according to which there are two principal reactions succeeding each other, it may be in quite contiguous places, but under different conditions. Where the nitrous fumes prevail and there is less water present, sulphur dioxide combines with nitrous acid and oxygen to form nitroso-sulphuric acid, a crystalline substance of the formula $\text{SO}_2(\text{OH})(\text{ONO})$. The reaction is therefore:— $\text{SO}_2 + \text{O} + \text{NO}_2\text{H} = \text{SO}_2\text{NH}$. The solid substance is, however, only exceptionally met with, as it at once dissolves in the mist of sulphuric acid floating in the chamber, and forms "nitrous vitriol." Wherever this nitrous vitriol comes into contact with liquid water (*not* steam), which is also present in the chamber in the shape of mist, and practically as dilute sulphuric acid, it is decomposed into sulphuric and nitrous acid, thus:— $\text{SO}_2(\text{OH})(\text{ONO}) + \text{H}_2\text{O} = \text{H}_2\text{SO}_4 + \text{NO}_2\text{H}$. The re-formed nitrous acid, although not stable, any more than is its anhydride, N_2O_3 , is nevertheless the "oxygen carrier" in question, as the products of its spontaneous decomposition, when meeting with other compounds, always react like nitrous acid itself and thus may transfer an indefinite quantity of oxygen to the corresponding quantities of SO_2 and H_2O , with the corresponding formation of H_2SO_4 . This theory at once explains, among other things, why the acid formed in the vitriol chambers always contains an excess of water (the second of the above-quoted reactions requiring the "mass action" of this excess), and why the external cooling produced by the contact of the chamber sides with the air is of great importance (*liquid* water in the shape of a mist of dilute sulphuric acid being necessary for the process).

The commercial production of sulphuric acid imperatively requires that the nitrogen oxides (which originally were always introduced in the shape of nitric acid) should be available as long as possible, before being lost mechanically or by reduction to the inactive forms of nitrous oxide or elementary nitrogen. The first step towards securing this requirement was taken as early as 1827 by Gay-Lussac, who discovered that the nitrous fumes, otherwise carried away from the lead chambers by the waste atmospheric nitrogen and oxygen, could be retained by bringing the gases into contact with moderately strong sulphuric acid, the result being the formation of nitroso-sulphuric acid: $2\text{H}_2\text{SO}_4 + \text{N}_2\text{O}_3 = 2\text{SO}_2(\text{OH})(\text{ONO}) + \text{H}_2\text{O}$, and the latter remaining dissolved in sulphuric acid as "nitrous vitriol." But this important invention was of little use until John Glover, about 1866, found that the nitrous vitriol could be most easily reintroduced into the process by subjecting it to the action of burner-gas, before this enters into the lead chambers, preferably after diluting it with chamber acid, that is, acid of from 65 to 70 per cent., H_2SO_4 , as formed in the lead chambers. The reaction is then: $2\text{SO}_2(\text{OH})(\text{ONO}) + \text{SO}_2 + 2\text{H}_2\text{O} = 3\text{H}_2\text{SO}_4 + 2\text{NO}$; that is to say, all the "nitre" is returned to the chambers in the shape of NO ; the sulphuric acid employed in the Gay-Lussac process is not merely recovered, but an additional quantity is formed from fresh SO_2 ; as the heat of the burner-gases also comes into play, much water is evaporated which supplies part of the steam required for the working of the chambers; and the acid issues from the apparatus in a "denitrated" and sufficiently concentrated state (78 to 80 per cent. H_2SO_4) to be used over

again for absorbing nitrous vapours or any other purpose desired. Since that time, in every properly appointed sulphuric acid manufactory, the following cycle of operations is carried out. To begin with, in the burners pyrites (or, as the case may be, brimstone or blende) is made to yield hot burner-gas, containing about 7 per cent. (in the case of brimstone 10 or 11 per cent.) of SO_2 . This, after having been deprived of most of the flue-dust, is passed through the "Glover tower," *i.e.*, an upright cylindrical or square tower, consisting of a leaden shell lined with heat- and acid-proof stone or brick, and loosely filled or "packed" with the same material, over which a mixture of acid from the Gay-Lussac tower and from the chambers trickles down in such proportions that it arrives at the bottom as denitrated acid of from 78 to 80 per cent. The gases then pass on to the "chambers," structures of lead, generally about 20 feet wide, 18 feet high, and 100 or 150 feet long. Several such chambers are usually combined to a "set," with a cubic capacity of as much as 150,000 cubic feet or even more. Here the gases meet with more nitrous vapours, and with steam, or with water, converted into a fine dust or spray. Here the reactions sketched above take place, so that "chamber-acid" as already described is formed, while a mixture of gases escapes containing all the atmospheric nitrogen, some oxygen in excess, about 0.5 per cent. of the total SO_2 , and some oxides of nitrogen. This gas is now passed through the Gay-Lussac tower, which somewhat resembles the Glover tower, but is usually filled with coke, over which sulphuric acid of about 80 per cent., H_2SO_4 , trickles down in sufficient quantity to retain the nitrous vapours. Ultimately the waste gas is drawn off by a chimney, or sometimes by mechanical means.

Of course a great many special improvements have been made in the plant and the working of chamber systems; of these we mention only some of the most important. By judiciously watching all stages of the process, by observing the draught, the strength of the acid produced, the temperature, and especially by frequent analyses of the gases, the yield of acid has been brought up to 98 per cent. of the theoretical maximum, with a loss of nitre sometimes as low as two parts to 100 of sulphur burned. The supply of the nitric acid required to make up this loss is obtained in England by "potting," that is, by decomposing solid nitrate of soda by sulphuric acid in a flue between the pyrites burners and the chambers. On the Continent makers generally prefer to employ liquid nitric acid, which is run through the Glover tower together with the nitrous vitriol. Although this method appears more troublesome, it allows the amount of nitre to be more easily and more accurately regulated. The size of the Glover towers, and more especially that of the Gay-Lussac towers, has been progressively increased, and thereby the cube of the lead chambers themselves has been diminished to a much greater extent. By improved "packing," the towers have been rendered more durable, and in the case of the Gay-Lussac tower, the loss of nitre has been diminished by avoiding the use of a coke packing, which acts upon that substance as a reducing agent. Many attempts have been made to reduce the chamber space by apparatus intended to bring about a better mixture of the gases, and to facilitate the interaction of the misty particles of nitrous vitriol and dilute acid floating in the chamber with each other, and with the chamber atmosphere. The earliest really successful, and still the most generally applied apparatus of this kind, is the Lunge-Rohrman "plate columns" or "reaction towers" placed between the chambers, but though this and similar apparatus has proved to be very useful in the later stages of the process, it has not been found practicable to do

away with the lead chambers entirely. The pumping of the acids up to the top of the towers is now always performed by means of compressed air, either in the old "acid eggs," or more economically in "pulsometers."

Most of the sulphuric acid manufactured is not required to be of higher strength than is furnished by the vitriol chambers, either directly (65 to 70 per cent.), or after a passage through the Glover tower (78 to 80 per cent.). This, for instance, holds good of the acid employed in the manufacture of sulphate of soda and hydrochloric acid from common salt, and in the manufacture of superphosphates. But for many purposes more highly concentrated acid is required. Until quite recently all such acid was made by boiling down the dilute acid, for which purpose a great variety of apparatus has been invented. The first question is always that of material. Lead can be used for the purpose only when the boiling-point of the acid is reduced by means of a vacuum—a plan which has not met with much success. Formerly glass vessels were generally employed and they still survive in England; but elsewhere they are not much used. Porcelain, enamelled iron, for high concentrations even cast-iron without any protection, are also in use. On the Continent platinum vessels have been for a long time almost universal, and they have been recently greatly improved by an internal lining of gold. The second consideration is the form of the vessels; these may be open pans or dishes, or closed retorts, or combinations of both. We also note the Faure and Kessler apparatus, which consists of a platinum pan, surmounted by a double-walled leaden hood, in such a manner that, while the hood is constantly cooled from the outside by water, the thin acid condensing on its inside is carried away without being allowed to flow back into the pan. The majority of acid makers, however, prefer retorts made entirely of platinum, preferably provided by the Heraeus process with a dense, closely adherent coating of gold, including the top or "dome." The new Kessler furnace is a very ingenious apparatus, in which the fire from a gas-producer travels over the sulphuric acid contained in a trough made of Volvic lava, and surmounted by a number of perforated plates, over which fresh acid is constantly running down; the temperature is kept down by the production of a partial vacuum, which greatly promotes the volatilization of the water, whilst retarding that of the acid. This furnace is also very well adapted for impure acids, unsuitable for platinum or platinum-gold stills on account of the crusts forming at the bottom of the retorts; and it is more and more coming into use both in Great Britain and on the Continent. A third consideration is the condensation of the vapours formed in the concentrating process; the further the concentration proceeds the more sulphuric acid they contain. Condensation is a comparatively easy task in the case of platinum apparatus, but with glass or porcelain beakers or retorts it presents great difficulties. In this respect the Kessler furnace has also proved to be very efficacious. The highest strength practically attainable by boiling down is 98 per cent. H_2SO_4 , and this is only exceptionally reached, since it involves much expenditure of fuel, loss of acid, and wear and tear of apparatus. The usual strength of the O.V. of commerce, mostly designated by its specific gravity as 168° Twaddell, is from 93 to 95, or at most 96 per cent. H_2SO_4 . When attempts are made to push the process beyond 98 per cent., it is found that the acid which distils over is as strong as that which remains behind. Real "monohydrate" or acid approaching 100 per cent. can be made by Lunge's process of cooling strong O.V. down to $-16^\circ C.$ when H_2SO_4 crystallizes out, or by the addition of anhydrous SO_3 in the shape of fuming acid.

Fuming or Nordhausen oil of vitriol, a mixture or

chemical compound of H_2SO_4 with more or less SO_3 , has been made for centuries by exposing pyritic schist to the influence of atmospheric agents, collecting the solution of ferrous and ferric sulphate thus formed, boiling it down into a hard mass ("vitriolstein") and heating this to a low red heat in small earthenware retorts. Since about 1800 this industry has been confined to the north-west of Bohemia, and it survived just till 1900, when it was entirely abandoned—not because its product had become any less necessary, but, quite on the contrary, because the enormously increasing demand for fuming sulphuric acid, arising through the discovery of artificial alizarine and other coal-tar colours, could not possibly be supplied by the clumsy Bohemian process. Other sources of supply had accordingly to be sought, and they were found by going back to a reaction known since the first quarter of the 19th century, when Doebereiner discovered the combination of SO_2 and O into SO_3 by means of spongy platinum. This reaction, now known by the name of the catalytic or contact process, was made the subject of a patent by Philips, in 1831, and was tried later in many ways, but had been always considered as useless for practical purposes until 1875, when it was simultaneously and independently taken up by Clemens Winkler in Freiberg, and by Squire and Messel in London. Both these inventors began in the same way, viz., by decomposing ordinary sulphuric acid by a high temperature into SO_2 , O, and H_2O (the last of course being in the shape of steam), absorbing the water by sulphuric acid, and causing the SO_2 and O to combine to SO_3 by means of moderately heated platinum in a fine state of division. Winkler showed that this division was best obtained by soaking asbestos with a solution of platinum chloride and reducing the platinum to the metallic state, and he described later a specially active kind of "contact substance," prepared from platinum chloride at a low temperature. This revival of the synthetical production of SO_3 , at a period when this article had suddenly become of great importance, caused the greatest excitement among chemists and led to numerous attempts in the same direction, some of which were at once sufficiently successful to compete with the Bohemian process. It was soon found that the production of a mixture of SO_2 and O from sulphuric acid, as above described, was both too troublesome and costly, and after a number of experiments in other directions inventors went back to the use of ordinary burner-gas from pyrites and sulphur burners. For a good many years the further development of this industry was surrounded by great mystery, but it is now known that a satisfactory solution of the difficulties existing in the above respect was attained in several places, for instance, at Freiberg and in London, by the labours of the original inventors, Professor Winkler and Dr Messel. These difficulties were mostly caused by the solid impurities contained in the burner-gases in the shape of flue-dust, especially the arsenic, which after a short time rendered the contact substance inactive, in a manner not as yet entirely understood. Another difficulty arose from the fact that the reaction $SO_2 + O = SO_3$ is reversible, the opposite reaction, $SO_3 = SO_2 + O$ setting in but little above the temperature required for the synthesis of SO_3 . As far as is known (so much secrecy having been observed) the best results obtained in various places, save one, did not exceed 67 per cent. of the theoretical quantity, the remaining 33 per cent. of SO_2 having to be converted into sulphuric acid in the ordinary lead chambers. As is now known, the exception (undoubtedly the only one until 1899) was the process discovered as early as 1889 by Dr Knietzsch, of the Badische Anilin-und-Soda-Fabrik, at Ludwigshafen, but kept strictly secret until 1899, when

the patents were published. The principal features of this invention are, first, a much more thorough purification of the burner-gas than had been practised up to that time, both in a chemical and a mechanical sense, and second, the prevention of superheating of the contact substance, which formerly always occurred by the heat generated in the process itself. As the Badische process effects this prevention by cooling the contact apparatus by means of the gaseous mixture to be later submitted to the catalytic action, the mixture is at the time heated up to the requisite temperature, and a considerable saving of fuel is the consequence. Altogether this process has been brought to such a pitch of simplicity and perfection, that it is cheap enough, not merely for the manufacture of fuming oil of vitriol of all strengths, but even for that of ordinary sulphuric acid of chamber-acid strength, while it is decidedly cheaper than the old process in the case of stronger acids, otherwise obtained by concentration by fire. It should be noted that these are not the results of a few years' working with an experimental plant, but of many years' work with large plant, now equal to a capacity of 120,000 tons of pyrites per annum. It is therefore not too much to say that, in all probability, the contact process will ultimately be employed generally for concentrated acids. Still, for the reasons given in the beginning of this article, the revolution thus impending will require a certain time for its accomplishment. Since the Badische process has become known, several other new contact processes have come into the field, in some of which ferric oxide is employed as contact substance, but we must refrain from describing these in detail.

Hydrochloric Acid and Sulphate of Soda.—As long as the Leblanc process was paramount in alkali manufacture, the decomposition of sodium chloride (common salt) by sulphuric acid was in the first instance carried on for the purpose of obtaining sulphate of soda, commercially known as "salt-cake." Hydrochloric acid (muriatic acid) was a necessary by-product of the reaction: $2\text{NaCl} + \text{H}_2\text{SO}_4 = \text{Na}_2\text{SO}_4 + 2\text{HCl}$, but in some cases it was altogether treated as a waste-product, which at the same time constituted a great nuisance. Generally it was more or less perfectly recovered, but only exceptionally was it utilized to the fullest possible extent. The technical progress of the manufacture of hydrochloric acid (comp. *Ency. Brit.* vol. v. p. 678, and vol. xxii. p. 243) was promoted, to an extent perhaps unique in the history of legislative efforts, by the passing of the Alkali Acts, in 1863, 1874, 1881, and 1892, owing to the exemplary way in which the duties as inspector under these Acts were carried out by the late Dr R. Angus Smith and his successors, who directed their efforts not merely to their primary duty of preventing nuisance, but quite as much to showing manufacturers how to make the most of the acid formerly wasted in one shape or another. Not merely Great Britain but all mankind has been immensely benefited by the labours of the British alkali inspectors, which were of course supplemented by the work of technical men in all the countries concerned. The scientific and technical principles of the condensation of hydrochloric acid are now thoroughly well understood, and it is possible to recover nearly the whole of it in the state of strong commercial acid, containing from 32 to 36 per cent. of HCl, although probably the majority of the manufacturers are still content to obtain part of the acid in a much weaker state, merely to satisfy the requirements of the law prescribing the prevention of nuisance. The principles of the condensation, that is of converting the gaseous HCl given off during the decomposition of common salt into a strong solution of hydrogen chloride in water, can be summarized in a few words. The vapours of HCl, which are

always diluted with air, sometimes to a very great extent, must be brought into the most intimate contact possible with water, which greedily absorbs the gas, forming ordinary hydrochloric acid, and this process must be carried so far that scarcely any HCl remains in the escaping gases. The maximum escape allowed by the Alkali Acts, viz., 5 per cent. of the total HCl, is far above that which is now practically attained. For a proper utilization of this condensed acid it is nearly always imperative that it should be as strong as possible, and this forms a second important consideration in the construction of the condensing apparatus. Since the solubility of HCl in water decreases with the increase of the temperature, it is necessary to keep the latter down—a task which is rendered somewhat difficult both by the original heat retained by the gases on their escape from the decomposing apparatus and by the heat given off through the reaction of HCl upon water.

Very different methods have been employed to effect all the above purposes. In Great Britain Gay-Lussac's coke towers, adapted by Gossage to the condensation of hydrochloric acid, are still nearly everywhere in use, frequently combined with a number of stone tanks through which the gas from the furnaces travels before entering the towers, meeting on its way the acid condensed in the tower. This process is excellent for effecting a complete condensation of the HCl as prescribed by the Alkali Acts, and for recovering the bulk of the acid in a tolerably strong state, but less so for recovering nearly the whole of it in the most concentrated state, although even this is occasionally attained. On the Continent, where the last-named requirement has been for a long time more urgent than in Great Britain, another system has been generally preferred, namely, passing the gas through a long series of stoneware receivers, and ultimately through a small tower packed with stoneware or coke, making the acid flow in the opposite direction to the gas. Great success has also been obtained by specially-constructed "plate towers" (already mentioned in connexion with their application to the manufacture of sulphuric acid), which allow both the coke towers and most of the stoneware receivers to be dispensed with.

Improvements in the construction of the condensing apparatus had to go hand in hand with those in the construction of the "salt-cake furnaces" for treating the common salt with sulphuric acid. The ordinary way of effecting this treatment is to carry out the first reaction in cast-iron pans or "pots," fired from below, and to complete it by applying a higher temperature in a "roasting-furnace." If the latter is constructed as a reverberatory furnace, where the HCl given off is mixed with the products of the combustion of the fuel, the acid obtained during this part of the operation is necessarily weak. It is therefore altogether preferable to construct the roasting-furnace as a "muffle," heated only on the outside, although the expenditure of more fuel is thus involved. The drawback formerly caused by leakages of acid gases into the fire-flues through cracks in the muffle has been removed by the construction of "plus-pressure furnaces." Many and often very costly attempts have been made to construct mechanical salt-cake furnaces. Of these Mactear's furnaces have met with the greatest success, though this is limited by the fact that, apart from their great cost, they yield the hydrochloric acid in a weaker state than hand-wrought furnaces. For this reason they have been abandoned in some places, and are not likely to be generally introduced. The same holds good of the "direct salt-cake process" of Hargreaves and Robinson, in which salt is subjected to the action of burner-gases and steam at a low red heat, thus effecting the reaction:

$2\text{NaCl} + \text{SO}_2 + \text{O} + \text{H}_2\text{O} = \text{Na}_2\text{SO}_4 + 2\text{HCl}$, without the intervention of lead chambers. This process, which requires complicated and costly plant, has been most ingeniously elaborated by the inventors, and has been made a perfect success for the manufacture of very pure sulphate of soda, also for the complete condensation of the HCl, but the latter is less easily obtained in the strong state possible with muffle furnaces, owing to the dilution of the gas with nitrogen, &c. (comp. *Ency. Brit.* vol. xxii. p. 242).

The manufacture of sodium sulphate and hydrochloric acid has been put on an entirely different economical basis through several great changes in the alkali industry, which have checked the further expansion of the Leblanc process. This process, which formerly absorbed most of the salt-cake produced, is giving place more and more to the ammonia-soda process, which starts directly from sodium chloride. Outside Great Britain the Leblanc process now plays a very subordinate part, and in Great Britain itself it will certainly not spread any farther and will probably ultimately succumb, although this may be in a somewhat remote future. The only other considerable outlet for salt-cake is the manufacture of glass, which naturally cannot be indefinitely extended. These circumstances, by restricting both the quantity and still more the value of the sodium sulphate, necessarily conferred a greater value upon the hydrochloric acid manufactured along with it; and as this acid was until recently indispensable for the production of chlorine, the enhanced price of bleaching-powder and chlorate of potash for a time compensated the manufacturer for his loss on the salt-cake, and thus again reacted favourably on the economical aspect of the Leblanc process. Much more attention is now devoted than formerly to the preparation of the hydrochloric acid in a strong state, and to processes intended to make it yield a greater amount of chlorine. The recent development of the electrolysis of the alkaline chlorides necessarily again decreases the value of the hydrochloric acid obtained in the manufacture of salt-cake, and must in the end lead to a further restriction in the production of the latter.

The Manufacture of Alkali.—The term "alkali" is usually applied to several sodium compounds, viz., the hydrate (caustic soda), the carbonate (soda-ash), and the bicarbonate. The corresponding potassium compounds are almost exclusively made in Germany, from Stassfurt salts, and in France, from the "vinasse" of beet-root manufactures. The alkali manufacture in this sense is intimately connected with the chlorine industry, and both have for a long time formed the most important of British chemical industries. In vol. xxii. p. 242 a description has been given of the two principal forms of the soda manufacture, viz., the Leblanc process and the ammonia-soda process. The *Leblanc process* was for a long time that by which nearly all alkali was made. During the last decade many improvements have been effected in all its stages, principally by the development of mechanical furnaces and by attention to details; in this connexion Dr Hurter's name should be especially mentioned. Its greatest drawback, viz., the loss of the sulphur originally introduced into the process, and formerly only imperfectly and at not sufficiently small cost recovered from the "tank-waste" by the processes of Mond and Schaffner, has been overcome by the Claus-Chance sulphur recovery process. This consists in decomposing the calcium sulphide of the tank-waste, which had been previously reduced to a thin watery paste, by means of impure carbonic acid in the shape of lime-kiln gas, and converting the resulting H_2S either into sulphuric acid, or, preferably, into a very pure form of free sulphur. Thus 85 per cent.

of the sulphur is recovered in a much more valuable form than it originally possessed in the shape of pyrites, and the remaining 15 per cent. as well as the solid residue of the operation are at least rendered innocuous.

In spite of these great improvements the Leblanc process cannot economically compete with the *ammonia-soda process*, principally for two reasons. The sodium in the latter costs next to nothing, being obtained from natural or artificial brine in which the NaCl possesses an extremely slight value. The fuel required is less than half the amount used in the Leblanc process. Moreover, the process has been gradually elaborated into a very complicated and costly, but perfectly regularly working scheme, in which the cost of labour and the loss of ammonia are reduced to a minimum. The only way in which the Leblanc process could still hold its own was by being turned in the direction of making caustic soda, to which it lends itself more easily than the ammonia-soda process; but the latter has recently invaded even this field. One advantage, however, still remained to the Leblanc process. All endeavours to obtain either hydrochloric acid or free chlorine in the ammonia-soda process turned out economical failures, all the chlorine of the sodium chloride being ultimately lost in the shape of worthless calcium chloride. The Leblanc process thus remained the sole purveyor of chlorine in its active shapes, and in this way the fact is accounted for that, at least in Great Britain, the Leblanc process still furnishes nearly half of all the alkali made, while in other countries its proportional share is very much less. The profit made upon the chlorine produced has to make up for the loss on the alkali.

But the position still held by the Leblanc process is seriously threatened by the development of the *electrolytic decomposition of the alkaline chlorides*, which has taken place principally since 1890. These processes possess some of the advantages of both the old processes. They start with the cheapest form of NaCl, viz., brine; and they at once furnish the most valuable form of alkali, viz., caustic soda, and at the same time either free chlorine, or, directly, bleaching-liquor of chlorates. Up to a certain stage they require no fuel, except for the production of energy, which may be furnished by the cheapest kind of motors,—best of all, by water-power. Only for the conversion of the strong solution of alkali obtained in the electrolytic cell into a solid form is some fuel indispensable. The great difficulties at first experienced with electrodes and diaphragms do not seem to exist any more; and so far as the production of *chlorine compounds* is concerned, there seems to be nothing to stop the triumph of electrolysis over the old processes, which were described in vol. v. p. 678. We must not omit to notice that the electrolysis of sodium chloride and the manufacture of alkali in a commercial shape are decidedly more difficult than the corresponding operations in the case of potassium chloride. But to the inroads of electrolysis into the domain of alkali manufacture, there is one natural limitation brought about by the fact that this process produces for each 40 parts of NaOH, equivalent to 53 parts of Na_2CO_3 , 35.5 parts of chlorine, which yield about 100 parts of bleaching-powder, whereas the present consumption of chlorine products is in the proportion of about one part of bleaching-powder (or its equivalent of chlorates) to five parts of alkali. Manifestly only that quantity of alkali can be made which corresponds to the sale of the chlorine products necessarily made at the same time, and this means that about nine-tenths of the alkali consumed must be made in other ways. As far as we can see, the ammonia-soda process will supply the principal portion of the great remainder, but for some time the Leblanc process will still contribute

a share, and "natural soda" from California, from Egypt, &c. (comp. vol. xxii. p. 240) will come in to a certain extent.

Nitric acid (comp. vol. xvii. p. 518).—The manufacture of this acid has been very largely extended, on account both of the enormously increased production of explosives for engineering and mining purposes and of the substitution of smokeless powders for the old gunpowder made from saltpetre. But it is still effected by the wasteful process of decomposing sodium nitrate by sulphuric acid, producing as residue "nitre-cake," a product of very little value. Several attempts have been made to decompose the nitrate in a more profitable way, e.g., by means of ferric oxide, in which case the soda is converted into the valuable shape of NaOH, and the ferric oxide is recovered as such; but none of these processes have emerged beyond the experimental stage. The old process has been improved on various sides, chiefly by the elaboration of more rational systems of condensation, and by conducting the operation in such a manner that it furnishes at once a maximum of strong and sufficiently pure acid, which does not need to be freed from the lower oxides of nitrogen by the process of "bleaching"; also by separating the decomposition of sodium nitrate into two stages and conducting it as a continuous process, with the employment of comparatively weak sulphuric acid even for the production of strong nitric acid (the Rhenania-Uebel process).

REFERENCES.—The principal work on acids and alkali is Lunge's *Sulphuric Acid and Alkali*, 2nd ed. 3 vols. 1891-96. The same work has also appeared in French (by Lunge and Naville), 3 vols. 1879-81, and in German, 2nd ed. 3 vols. 1893-96. The same author has given a synopsis of the manufacture of sulphuric acid up to 1899 in his article "Schwefel" in Muspratt's *Chemie*, 4th ed. vii. 1114-1368. Acireale, a town and episcopal see of the province of Catania, Sicily, Italy, 9 miles N. by E. from Catania by rail. It has a school of the industrial arts and sciences. Population, 25,900 (1881); 35,459 (1901).

Acland, Sir Henry Wentworth Dyke, BART. (1815-1900), British medical professor and man of learning, was born 23rd August 1815, and was the fourth son of Sir Thomas Dyke Acland. He was educated at Harrow and Christ Church, was elected Fellow of All Souls' in 1841, and, following the medical profession, took his Oxford degree of M.D. in 1848, having in 1845 been appointed Lee's Reader in Anatomy. The revival of medical study and the introduction of the study of natural science into Oxford were in great measure due to Sir Henry Acland. He promoted in every way the foundation of laboratories and of the Oxford Museum, formed an extensive series of physiological preparations on the plan of John Hunter, and did far more to overcome the indifference and remove the suspicion generally prevalent when he commenced his labours than could have been achieved by one less generally acceptable from his birth, his amenity, and the elevation of his character. "To Henry Acland," says Ruskin, "physiology was an intrusted gospel of which he was the solitary preacher to the heathen." On the other hand, as has been well observed, his thorough classical training preserved science at Oxford from too abrupt a severance from the humanities. In conjunction with his intimate friend, Dean Liddell, he revolutionized the study of art and archæology, so that the cultivation of these subjects, for which, as Ruskin declared, no one at Oxford cared before their time, began to flourish in the University. He published a memoir on the visitation of

cholera in 1854, and another on the topography of the Troad; but his claims to remembrance rest chiefly on his systematic, sedulous, and successful promotion of his favourite objects. He was Radcliffe librarian (1851), Regius Professor of Medicine (1858), and president of the General Medical Council from 1874 to 1887; he was also a curator of the University Galleries and of the Bodleian library. He was created a baronet in 1890. He resigned the Regius Professorship in 1894, and died in October 1900.

Acoustics.—The original article in the ninth edition of this *Encyclopædia* (hereafter referred to as O. A.) contains an account of many of the leading phenomena of acoustics and their elementary theory, so that it is only necessary here to supplement that account by discussing certain theoretical points, and by describing certain phenomena and methods of investigation which have been brought into more prominent notice, or have been discovered, in recent years.

The following elementary method of obtaining the velocity of plane waves of longitudinal disturbance in air brings into prominence the fact that the velocity depends on and varies slightly with the excess Velocity of sound. and defect of pressure from the normal or undisturbed value. The method with appropriate modification will give the velocity of transverse disturbance in strings and longitudinal disturbance in rods. We suppose that a disturbance, the same at every point in a plane perpendicular to the direction of propagation, is in some way made and started in the air, and that external forces are applied to every particle in such a manner that the disturbance is constrained to move on with uniform velocity unchanged in form. The force per unit mass can be expressed in terms of the pressures due to the state of strain together with the applied force, and it can also be expressed in terms of the acceleration which is obtained from the condition that the disturbance moves on unchanged in form with constant velocity U . For this implies that the change in velocity of a particle at a given point during a small time dt is equal to the difference in the velocities at a given instant at that point, and at a point a distance Udt back along the line of propagation.

In Fig. 1 let QP represent the displacement curve of the disturbance (O. A. § 12). Let NM represent two points distant Udt apart along the line of propagation. Let MP, NQ, represent at a given instant the displacements of the particles which were originally at rest at M, N, but which are now displaced in the direction of propagation by amounts proportional to MP and NQ. Let u_M, u_N represent the velocities of the particles. Then the velocity of the M particle will change from u_M to u_N in time dt , so that the acceleration a is given by

Fig. 1.

$$a = \frac{u_N - u_M}{dt} = U \frac{u_N - u_M}{NM} \quad (1)$$

since $NM = Udt$.

But, drawing the tangent PT at P, the velocity at P is the rate at which the displacement is growing at P as the displacement curve travels along, and this is evidently at the rate TS per time taken by the disturbance to travel over NM.

Then
$$u_M = \frac{TS}{dt} = U \frac{TS}{NM} \quad (2)$$

This may be written as $-U \frac{dy}{dx}$. But we may express the pressure excess at M in terms of the displacement. For if the layer of air originally between M and N were all compressed as it is at P, the surface through N would be displaced forward NT, while that through M would only be displaced forward MP, or there would be a compression TS in length MN. Since the disturbance is purely longitudinal, this implies that there is a diminution of

volume proportional to TS in volume proportional to MN, or if v is the decrease of volume per original volume V ,

$$\frac{v}{V} = \frac{TS}{MN}$$

But if E is the elasticity of the air, and if p_M is the excess of pressure producing the decrease of volume, by definition we have

$$p_M = E \frac{v}{V} = E \frac{TS}{MN}$$

from (2)
$$= \frac{E}{U} u_M \quad \dots \quad (3)$$

This relation shows that wherever the particle velocity is forward p_M is in excess, and that wherever it is backward p_M is in defect of the undisturbed or normal pressure.

We may evidently put $p_M = -E \frac{dy}{dx}$.

Forming a similar expression for p_N and subtracting

$$p_N - p_M = \frac{E}{U} (u_N - u_M),$$

and substituting in (1)

$$a = \frac{U^2}{E} \frac{p_N - p_M}{NM} \quad \dots \quad (4)$$

Turning now to the forces acting on the layer originally between M and N and 1 sq. cm. in cross section, we have $P + p_N$ at N and $P + p_M$ at M , where P is the normal pressure. There is also the applied force. If this is X per mass 1, and if the normal density is ρ , then the total force on mass ρMN is

$$p_N - p_M + X \rho MN,$$

and the acceleration is

$$a = \frac{p_N - p_M}{\rho NM} + X \quad \dots \quad (5)$$

Equating (4) and (5) we obtain

$$U^2 = \frac{E}{\rho} \left(1 + \frac{\rho \cdot NM \cdot X}{p_N - p_M} \right) \quad \dots \quad (6)$$

If the disturbance is so small that the change in volume may be taken as exactly proportional to the change in pressure, then E is constant. If then $X=0$, or there is no external applied force,

$$U^2 = E/\rho$$

(the value found in O. A. § 15). But if the disturbance is great we can no longer assume that E is the same for all changes of volume. We may, however, suppose that the change of pressure consists of two terms: (1) a term exactly proportional to the change in volume; (2) a term, in general very small, expressing the divergence from proportionality. If we like, we may regard the second term as an applied force superposed on the force expressed in the first term, and then trace the effect in equation (6). The relation between pressure and volume in air for sound disturbance is the adiabatic relation

$$PV^\gamma = \text{constant},$$

where γ =ratio of specific heats. If P change to $P+p$ and V to $V-v$,

$$(P+p)(V-v)^\gamma = PV^\gamma,$$

or

$$1 + \frac{p}{P} = \left(1 - \frac{v}{V} \right)^\gamma.$$

Expanding the right hand and neglecting powers above the second,

$$\frac{p}{P} = \frac{v}{V} + \gamma \frac{(\gamma+1)}{2} \frac{v^2}{V^2}.$$

If the second term on the right did not exist, we should have

$$p = \gamma P \frac{v}{V},$$

and the elasticity would have the constant value

$$E = \gamma P.$$

We assume now that the elasticity does have this value, and that the second term is an applied force superposed on the pressures deduced from a constant elasticity which were used in obtaining equation (6). In that equation we must take the applied force on element cross section 1^2 , length NM , as

$$\rho \cdot NM \cdot X = \text{excess of pressure denoted by second term at } N,$$

$$= \gamma \frac{\gamma+1}{2} P \cdot \left\{ \left(\frac{v}{V} \right)_N^2 - \left(\frac{v}{V} \right)_M^2 \right\}.$$

Now in the denominator of the fraction in (6), $p_N - p_M$ represents pressures deduced from a constant elasticity, so that,

$$p_N - p_M = E \left\{ \left(\frac{v}{V} \right)_N - \left(\frac{v}{V} \right)_M \right\}.$$

Substituting these values in (6),

$$U^2 = \frac{E}{\rho} \left[1 + \gamma \frac{\gamma+1}{2E} P \left\{ \left(\frac{v}{V} \right)_N + \left(\frac{v}{V} \right)_M \right\} \right] \\ = \frac{E}{\rho} \left\{ 1 + (\gamma+1) \frac{v}{V} \right\}$$

(since $E = \gamma P$ and $\left(\frac{v}{V} \right)_N$ is in the limit equal to $\left(\frac{v}{V} \right)_M$)

$$= \frac{E}{\rho} \left(1 + \frac{\gamma+1}{\gamma} \frac{p}{P} \right) \\ = \frac{E}{\rho} \left(1 + (\gamma+1) \frac{u}{U} \right) \quad \text{from (3)}$$

or

$$U = \sqrt{\frac{E}{\rho}} \left(1 + \frac{\gamma+1}{2} \frac{u}{U} \right) \\ = \sqrt{\frac{E}{\rho}} + \frac{\gamma+1}{2} u \quad \dots \quad (7)$$

This result implies that the different parts of a wave move on at different rates, so that its form must change. As we obtained the result on the supposition of unchanged form, we

can of course only apply it for such short lengths and such short times that the part dealt with does not appreciably alter. We see at once that, where $u=0$, the velocity has its "normal" value, while where u is positive the velocity is in excess, and where u is negative the velocity is in defect of the normal value.

Fig. 2.

If, then, a (Fig. 2) represent the displacement curve of a train of waves, b will represent the pressure excess and particle velocity, and from (7) we see that while the nodal conditions of b , with $p=0$ and $u=0$, travel with velocity $\sqrt{\frac{E}{\rho}}$, the crests exceed that velocity by $\frac{\gamma+1}{2} u$,

and the hollows fall short of it by $\frac{\gamma+1}{2} u$, with the result that the fronts of the pressure waves become steeper and steeper, and the train b changes into something like c . If the steepness get very great our investigation ceases to apply, and neither experiment nor theory has yet shown what happens. Probably there is a breakdown of the wave somewhat like the breaking of a water-wave when the crest gains on the next trough. In ordinary sound-waves the effect of the particle velocity in affecting the velocity of transmission must be very small.

Experiments, referred to later, have been made to find the amplitude of swing of the air particles in organ pipes. Thus Mach found an amplitude 0.2 cm. when the issuing waves were 250 cm. long. The amplitude in the pipe was probably much greater than in the issuing waves. Let us take it as 0.1 mm. in the waves—a very extreme value. The maximum particle velocity is $2\pi na$ (where n is the frequency and a the amplitude), or $2\pi aU/\lambda$. This gives maximum u =about 80 cm./sec., which would not seriously change the form of the wave in a few wave lengths. Meanwhile the waves are spreading out and the value of u is falling in inverse proportion to the distance from the source, so that very soon its effect must become negligible.

But in loud sudden sounds, such as a peal of thunder or the report of a gun, the effect may be more considerable, and there is no doubt that with such sounds the normal velocity is quite considerably exceeded. Thus there is the old observation of Parry (§ 23, O. A.) that from a distance

the report of a gun was heard before the word "Fire." More recently Jaques (*Phil. Mag.* 1879, vii. p. 219) has investigated the transmission of the report from a cannon in different directions, finding that it rose to a maximum of 1267 ^{ft.}/_{sec.} at 70 to 90 feet in the rear, and then fell off. If, too, the sound be confined in pipes so that the intensity cannot diminish rapidly the normal velocity is exceeded. Thus Regnault in his classical experiments (*Phil. Mag.* 1868, xxxv. p. 161) found that the velocity of the report of a pistol carried through a pipe diminished with the intensity, and his results have been confirmed by Violle and Vautier (*Phil. Mag.* 1888, xxvi. p. 77). Possibly the prolonged boom into which the report of a gun changes at a distance is due to some kind of break-down and lengthening out of the original disturbance when the front of the pressure wave becomes impossibly steep.

Some light has been thrown on the curious "whispering gallery" case of reflection of sound by observations made by Lord Rayleigh in the circular gallery at the base of the dome of St. Paul's Cathedral. An old explanation of the effect consisted in ascribing it to the concentration of the sound rays after single reflection from the surface to a focus conjugate to the source, or to the crowding in a caustic (O. A. § 38). But Lord Rayleigh finds that "the abnormal loudness with which a whisper is heard is not confined to the position diametrically opposite to that occupied by the whisperer, and therefore, it would appear, does not depend materially upon the symmetry of the dome. The whisper seems to creep round the gallery horizontally, not necessarily along the shorter arc, but rather along that arc towards which the whisperer faces. This is a consequence of the very unequal audibility of a whisper in front and behind the speaker, a phenomenon which may easily be observed in the open air" (*Sound*, ii. § 287).

Let Fig. 3 represent a horizontal section of the dome through the source P. Let OPA be the radius through P. Let PQ represent a ray of sound making θ with the tangent at A. Let ON = OP cos θ be the perpendicular on PQ. Then the reflected ray QR and the ray reflected at R, and so on, will all touch the circle drawn with ON as radius. A ray making less than θ with the tangent will with its reflections touch a larger circle. Hence all rays between $\pm\theta$ will be confined in the space between the outer dome and a circle of radius OP cos θ , and the weakening of intensity will be chiefly due to vertical spreading.

Fig. 3.

Rayleigh points out that this clinging of the sound to the surface of a concave wall does not depend on the exactness of the spherical form. He suggests that the propagation of earthquake disturbances is probably affected by the curvature of the surface of the globe, which may act like a whispering gallery.

In some cases of echo, when the original sound is a compound musical note, the octave of the fundamental tone is reflected much more strongly than that tone itself. This is explained by Rayleigh (*Sound*, ii. § 296) as a consequence of the irregularities of the reflecting surface. The irregularities send back a scattered reflection of the different incident trains, and this scattered reflection becomes more copious the shorter the wave length. Hence the octave, though comparatively feeble in the incident train, may predominate in the scattered reflection constituting the echo.

Osborne Reynolds (*Proc. R. S.* xxii. 1874, p. 531) first pointed out that refraction would result from a variation in the temperature of the air at different heights. The velocity of sound in air is independent of the pressure, but varies with the temperature, its value at t° C. being (O. A. § 18)—

$$U = U_0 \left(1 + \frac{at}{2} \right),$$

where U_0 is the velocity at 0° C., and a is the coefficient of expansion $\cdot 00365$. Now if the temperature is higher overhead than at the surface, the velocity overhead is greater. If a wave front is in a given position, as a 1 (Fig. 4), at a given instant, the upper part moving faster

Fig. 4.

gains on the lower, and the front tends to swing round as shown by the successive positions a 2, 3, and 4; that is, the sound tends to come down to the surface. This is well illustrated by the remarkable horizontal carriage of sound on a still clear frosty morning, when the surface layers of air are decidedly colder than those above. At sunset, too, after a warm day, if the air is still, the cooling of the earth by radiation cools the lower layers, and sound carries excellently over a level surface. But usually the lower layers are warmer than the upper layers, and the velocity below is greater than the velocity above. Consequently a wave front such as b 1 tends to turn upwards, as shown in the successive positions b 2, 3, and 4. Sound is then not so well heard along the level, but may still reach an elevated observer. On a hot summer's day the temperature of the surface layers may be much higher than that of the higher layers, and the effect on the horizontal carriage of sound may be very marked.

It is well known that sound travels far better with the wind than against it. Stokes showed that this effect is one of refraction, due to variation of velocity of the air from the surface upwards (*B. A. Rep. Refraction by wind.* 1857, p. 22). It is, of course, a matter of common observation that the wind increases in velocity from the surface upwards. An excellent illustration of this increase was pointed out by Osler in the shape of old clouds; their upper portions always appear dragged forward, and they lean over, as it were, in the direction in which the wind is going. The same kind of thing happens with sound-wave fronts when travelling with the wind.

The velocity of any part of a wave front relative to the ground will be the normal velocity of sound + the velocity of the wind at that point. Since the velocity increases as we go upwards, the front tends to swing round and travel downwards, as shown in the successive positions a 1, 2, 3, and 4, in Fig. 4, when we must suppose the wind to be blowing from left to right. But if the wind is against the sound the velocity of a point of the wave front is the normal velocity — the wind velocity at the point, and so decreases as we rise. Then the front tends to swing round and travel upwards as shown in the successive positions b 1, 2, 3, and 4, in Fig. 4, where the wind is travelling from right to left. In the first case the waves are more likely to reach and be perceived by an observer level with the source, while in the second case they may go over his head and not be heard at all.

Many of the well-known phenomena of optical diffraction may be imitated with sound-waves, especially if the waves be short. Lord Rayleigh has given various examples, and accounts of experiments and theory will be found in his *Sound*, vol. ii.

A simple mode of forming Lissajous figures, to find the ratio of the frequencies of two forks, consists in attaching two small plane mirrors, one on the prong of one fork, the other on a prong of another fork. The two forks are arranged so that one vibrates in a vertical, the other in a horizontal plane, and they are so placed that a converging beam of light, received in one mirror, is reflected to the

other and then brought to a point on a screen. If the first fork alone vibrates, the point on the screen appears lengthened out into a vertical line through the changes in inclination of the first mirror, while if the second fork alone vibrates, the point appears lengthened out into a horizontal line. If both vibrate, the point describes a curve which appears continuous through the persistence of the retinal impression. The curve is named a Lissajous figure after the deviser of this method of investigation. Lissajous also obtained the figures by aid of the vibration microscope, an instrument which he invented. Instead of a mirror, the objective of a microscope is attached to one prong of the first fork and the eye-piece of the microscope is fixed behind the fork. Instead of a mirror the second fork carries a bright point on one prong, and the microscope is focussed on this. If both forks vibrate, an observer looking through the microscope sees the bright point describing Lissajous figures. If the two forks have the same frequency, it is easily seen that the figure will be an ellipse (including as limiting cases, depending on relative amplitude and phase, a circle and a straight line). If the forks are not of exactly the same frequency the ellipse will slowly revolve, and from its rate of revolution the ratio of the frequencies may be determined (Rayleigh, *Sound*, i. § 33). If one is the octave of the other a figure of 8 may be described, and so on.

Koenig has devised a clock in which a fork of frequency 64 takes the place of the pendulum (*Wied. Ann.* ix. p. 394, 1880). The motion of the fork is maintained by the clock acting through an escapement, and the dial registers both the number of vibrations of the fork and the seconds, minutes, and hours. By comparison with a clock of known rate the total number of vibrations of the fork in any time may be accurately determined. One prong of the fork carries a microscope objective, part of a vibration microscope, of which the eye-piece is fixed at the back of the clock, and the Lissajous figure made by the clock fork and any other fork may be observed. With this apparatus Koenig studied the effect of temperature on a standard fork of 256 frequency, and found that the frequency decreased by $\cdot 0286$ of a vibration for a rise of 1° , the frequency being exactly 256 at 26.2° C. Hence the frequency may be put as $256 \{1 - \cdot 000113 (t - 26.2)\}$.

Koenig also used the apparatus to investigate the effect on the frequency of a fork of a resonating cavity placed near it. He found that when the pitch of the cavity was below that of the fork the pitch of the fork was raised, and *vice versa*. But when the pitch of the cavity was exactly that of the fork when vibrating alone, though it resounded most strongly, it did not affect the frequency of the fork. These effects have been explained by Lord Rayleigh (*Sound*, i. § 117).

In the stroboscopic method of McLeod and Clarke, the full details of which will be found in the original memoir (*Phil. Trans.* 1880, part i. p. 1), a cylinder is ruled with equidistant white lines parallel to the axis on a black ground. It is set so that it can be turned at any desired and determined speed about a horizontal axis, and when going fast enough it appears grey. Imagine now that a fork with black prongs is held near the cylinder with its prongs vertical and the plane of vibration parallel to the axis, and suppose that we watch the outer outline of the right-hand prong. Let the cylinder be rotated so that each white line moves exactly into the place of the next while the prong moves once in and out. Hence when a white line is in a particular position on the cylinder, the prong will always be the same distance along it and cut off the same length from view. The

most will be cut off in the position of the lines corresponding to the furthest swing out, then less and less till the furthest swing in, then more and more till the furthest swing out, when the appearance will be exactly as at first. The boundary between the grey cylinder and the black fork will therefore appear wavy with fixed undulations, the distance from crest to crest being the distance between the lines on the cylinder. If the fork has slightly greater frequency, then a white line will not quite reach the next place while the fork is making its swing in and out, and the waves will travel against the motion of the cylinder. If the fork has slightly less frequency the waves will travel in the opposite direction, and it is easily seen that the frequency of the fork is the number of white lines passing a point in a second \pm the number of waves passing the point per second. This apparatus was used to find the temperature coefficient of the frequency of forks, the value obtained $-\cdot 00011$ being the same as that found by Koenig. Another important result of the investigation was that the phase of vibration of the fork was not altered by bowing it, the amplitude alone changing. The method is easily adapted for the converse determination of speed of revolution when the frequency of a fork is known.

The phonic wheel, invented independently by La Cour and Lord Rayleigh (see *Sound*, i. § 68 c), consists of a wheel carrying several soft iron armatures fixed at equal distances round its circumference. *Rayleigh's
phonic
wheel.* The wheel rotates between the poles of an electro-magnet, which is fed by an intermittent current such as that which is working an electrically maintained tuning-fork (see *infra*). If the wheel be driven at such rate that the armatures move one place on in about the period of the current, then on putting on the current the electro-magnet controls the rate of the wheel so that the agreement of period is exact, and the wheel settles down to move so that the electric driving forces just supply the work taken out of the wheel. If the wheel has very little work to do it may not be necessary to apply driving power, and uniform rotation may be maintained by the electro-magnet. In an experiment described by Rayleigh such a wheel provided with four armatures was used to determine the exact frequency of a driving fork known to have a frequency near 32. Thus the wheel made about 8 revolutions per second. There was one opening in its disc, and through this was viewed the pendulum of a clock beating seconds. On the pendulum was fixed an illuminated silver bead which appeared as a bright point of light when seen for an instant. Suppose now an observer to be looking from a fixed point at the bead through the hole in the phonic wheel, he will see the bead as 8 bright points flashing out in each beat, and in succession at intervals of $\frac{1}{8}$ second. Let us suppose that he notes the positions of two of these next to each other in the beat of the pendulum one way. If the fork makes exactly 32 vibrations and the wheel 8 revolutions in one pendulum beat, then the positions will be fixed, and every two seconds, the time of a complete pendulum vibration, he will see the two positions looked at flash out in succession at an interval of $\frac{1}{8}$ second. But if the fork has, say, rather greater frequency, the hole in the wheel comes round at the end of the two seconds before the bead has quite come into position, and the two flashes appear gradually to move back in the opposite way to the pendulum. Suppose that in N beats of the clock the flashes have moved exactly one place back. Then the first flash in the new position is viewed by the $8N$ th passage of the opening, and the second flash in the original position of the first is viewed when the pendulum has made exactly N beats and by the $(8N + 1)$ th passage of the hole. Then

*McLeod
and
Clarke's
stroboscopic
method.*

the wheel makes $8N + 1$ revolutions in N clock beats, and the fork makes $32N + 4$ vibrations in the same time. If the clock is going exactly right, this gives a frequency for the fork of $32 + \frac{4}{N}$. If the fork has rather less frequency than 32 then the flashes appear to move forward and the frequency will be $32 - \frac{4}{N}$. In Rayleigh's experiment the

32 fork was made to drive electrically one of frequency about 128, and somewhat as with the phonic wheel, the frequency was controlled so as to be exactly 4 times that of the 32 fork. A standard 128 fork could then be compared either optically or by beats with the electrically driven 128, and the frequency of the standard determined.

A very noticeable illustration of the alteration of pitch by motion occurs when a whistling locomotive moves rapidly past an observer. As it passes, the pitch of the whistle falls quite appreciably. The explanation is simple. The engine follows up any wave that it has sent forward, and so crowds up the succeeding waves into a less distance than if it remained at rest. It draws off from any wave it has sent backward and so spreads the succeeding waves over a longer distance than if it had remained at rest. Hence the forward waves are shorter and the backward waves are longer. Since $U = n\lambda$ where U is the velocity of sound, λ the wave length, and n the frequency, it follows that the forward frequency is greater than the backward frequency.

The more general case of motion of source, medium, and receiver, may be treated very easily if the motions are all in the line joining source and receiver. Let S (Fig. 5) be the source at a given instant, and let its frequency of vibration, or the number of waves it sends out per second, be n . Let S' be its position, one second later, its velocity being u . Let R be the receiver at a given instant, R' its position a second later, its velocity being v . Let the velocity of the air from S to R be w , and let U be the velocity of sound in still air. If all were still, the n waves emitted by S in one second would spread over a length U . But through the wind velocity the first wave is carried to a distance

Fig. 5.

$U + w$ from S , while through the motion of the source the last wave is a distance u from S . Then the n waves occupy a space $U + w - u$. Now turning to the receiver, let us consider what length is occupied by the waves which pass him in one second. If he were at rest, it would be the waves in length $U + w$, for the wave passing him at the beginning of a second would be so far distant at the end of the second. But through his motion v in the second, he receives only the waves in distance $U + w - v$. Since there are n waves in distance $U + w - v$ the number he actually receives is

$$n \frac{U + w - v}{U + w - u}$$

If the velocities of source and receiver are equal then the frequency is not affected by their motion or by the wind. But if their velocities are different, the frequency of the waves received is affected both by these velocities and by that of the wind.

The change in pitch through motion of the source may be illustrated by putting a pitch-pipe in one end of a few feet of rubber tubing and blowing through the other end, while the tubing is whirled round the head. An observer in the plane of the motion can easily hear a change in the pitch as the pitch-pipe moves to and from him.

A musical note has a definite pitch or frequency, that is, it is a disturbance of definite periodicity. Yet notes of the same pitch, emitted by different instruments, have quite different timbre or quality. The three characteristics of a longitudinal periodic disturbance are its amplitude, the length after which it repeats itself, and its form which may be represented by the shape of the displacement curve. Now the amplitude

evidently corresponds to the loudness, and the length of period corresponds to the pitch or frequency. Hence we must put down the quality or timbre as depending on the form.

The simplest form of wave, so far as our sensation goes, that is, the one giving rise to a pure tone, is, we have every reason to suppose, one in which the displacement is represented by a harmonic curve or a curve of sines,

$$y = a \sin m(x - e)$$

If we put this in the form

$$y = a \sin \frac{2\pi}{\lambda}(x - e),$$

we see that $y = 0$, for $x = e, e + \frac{\lambda}{2}, e + \frac{3\lambda}{2}, e + \frac{5\lambda}{2}$, and so on, that y is $+$ from $x = e$ to $x = e + \frac{\lambda}{2}$, $-$ from $e + \frac{\lambda}{2}$ to $e + \frac{3\lambda}{2}$, and so on, and that it alternates between the values $+a$ and $-a$.

The form of the curve is evidently as represented in Fig. 6, and it may easily be drawn to exact scale from a table of sines.

Fig. 6.

In this curve $ABCD$ are nodes. $OA = e$ is termed the epoch, being the distance from O of the first ascending node. AC is the shortest distance after which the curve begins to repeat itself; this length λ is termed the wave length. The maximum height of the curve $HM = a$ is the amplitude. If we transfer O to $A, e = 0$, and the curve may be represented by

$$y = a \sin \frac{2\pi x}{\lambda}$$

If now the curve moves along unchanged in form in the direction ABC with uniform velocity U , the epoch $e = OA$ at any time t will be Ut , so that the value of y may be represented as

$$y = a \sin \frac{2\pi}{\lambda}(x - Ut) \quad (1)$$

The velocity perpendicular to the axis of any point on the curve at a fixed distance x from O is

$$\frac{dy}{dt} = -\frac{2\pi Ua}{\lambda} \cos \frac{2\pi}{\lambda}(x - Ut) \quad (2)$$

The acceleration perpendicular to the axis is

$$\begin{aligned} \frac{d^2y}{dt^2} &= -\frac{4\pi^2 U^2 a}{\lambda^2} \sin \frac{2\pi}{\lambda}(x - Ut) \\ &= -\frac{4\pi^2 U^2}{\lambda^2} y, \end{aligned}$$

which is an equation characteristic of simple harmonic motion.

The chief experimental basis for supposing that a train of longitudinal waves with displacement curve of this kind arouses the sensation of a pure tone, is that the more nearly a source is made to vibrate with a single simple harmonic motion, and therefore, presumably, the more nearly it sends out such a harmonic train, the more nearly does the note heard approximate to a single pure tone.

The average energy per cc. of a harmonic train of waves may easily be calculated. If ρ is the density, the kinetic energy in a length λ parallel to ABC , of cross-section 1 sq. cm., is

$$\begin{aligned} &\frac{1}{2} \int_0^\lambda \rho \left(\frac{dy}{dt} \right)^2 dx \\ &= \frac{\rho}{2} \int_0^\lambda \frac{4\pi^2 U^2 a^2}{\lambda^2} \cos^2 \frac{2\pi}{\lambda}(x - Ut) dx \quad \text{from (2)} \\ &= \frac{\rho \pi^2 U^2 a^2}{\lambda} \end{aligned}$$

The potential energy in volume cross section 1 length dx , manifested by the strain, may be calculated since it is equal to average pressure \times strain produced,

$$\text{or} \quad \left(P + \frac{p}{2} \right) v dx,$$

where p is the pressure excess and v the volume change per unit volume.

Now from equation (3) in the investigation of the velocity of sound (*supra*), we see that

$$p = -E \frac{dy}{dx},$$

while putting $V=1$

$$v = -\frac{dy}{dx}.$$

Inserting these values and integrating the potential energy between $x=0$ and $x=\lambda$, we have

$$-\int_0^\lambda \left(P - \frac{E}{2} \frac{dy}{dx} \right) \frac{dy}{dx} dx = -P \int_0^\lambda \frac{dy}{dx} dx + \frac{E}{2} \int_0^\lambda \left(\frac{dy}{dx} \right)^2 dx.$$

But differentiating (1) above

$$\frac{dy}{dx} = \frac{2\pi a}{\lambda} \cos \frac{2\pi}{\lambda} (x - Ut),$$

and as this has equal + and - values over a length $x=\lambda$, the first integral = 0. The second gives on integration

$$\frac{\pi^2 E a^2}{\lambda}$$

Then, since $E=\rho U^2$, the potential energy in one wave length, cross section 1,

$$= \frac{\rho \pi^2 U^2 a^2}{\lambda}$$

The total energy, kinetic + potential, in a length λ of cross section 1 is equally divided between the two kinds, and is

$$\frac{2\rho \pi^2 U^2 a^2}{\lambda}$$

If we regard this energy as travelling on with velocity U , the quantity passing across one sq. cm. in one second is U/λ times as great, or

$$\frac{2\rho \pi^2 U^3 a^2}{\lambda^2}$$

This gives the measure of the intensity of the sound on the supposition that loudness or intensity is to be measured by energy received per sq. cm. per second. From the values of the particle velocity and the pressure excess, it is easy to express the intensity in terms of these quantities.

Any periodic curve may be resolved into sine or harmonic curves by Fourier's theorem.

Fourier's theorem.

Suppose that any periodic sound disturbance, consisting of plane waves, is being propagated in the direction ABCD, Fig. 7. Let it be represented by

Fig. 7.

a displacement curve AHBKC. Its periodicity implies that after a certain distance the displacement curve exactly repeats itself. Let AC be the shortest distance after which the repetition occurs, so that CLDME is merely AHBKC moved on a distance AC. Then $AC = \lambda$ is the wave length or period of the curve. Let ABCD be drawn at such level that the areas above and below it are equal; then ABCD is the axis of the curve. Since the curve represents a longitudinal disturbance in air it is always continuous, at a finite distance from the axis, and with only one ordinate for each abscissa.

Fourier's theorem asserts that such a curve may be built up by the superposition, or addition of ordinates, of a series of sine curves of wave lengths $\lambda, \frac{\lambda}{2}, \frac{\lambda}{3}, \frac{\lambda}{4}, \dots$ if the amplitudes a, b, c, \dots and the epochs e, f, g, \dots are suitably adjusted, and the proof of the theorem gives rules for finding these quantities when the original curve is known. We may therefore put

$$y = a \sin \frac{2\pi}{\lambda} (x - e) + b \sin \frac{4\pi}{\lambda} (x - f) + c \sin \frac{6\pi}{\lambda} (x - g) + \text{etc.} \quad (1)$$

where the terms may be infinite in number, but always have wave lengths submultiples of the original or fundamental wave length λ . Only one such resolution of a given periodic curve is possible, and each of the constituents repeats itself not only in its own wave

length λ/n , but also evidently in the fundamental wave length λ . The successive terms of (1) are called the *harmonics of the first term*.

It follows from this that any periodic disturbance in air can be resolved into a definite series of simple harmonic disturbances of wave lengths equal to the original wave length and its successive submultiples, and each of these would separately give the sensation of a pure tone. If the series were complete, we should have terms which separately would correspond to the fundamental, its octave, its twelfth, its double octave, and so on. Now we can see that two notes of the same pitch, but of different quality, or different form of displacement curve, will, when thus analysed, break up into series having the same harmonic wave lengths; but they may differ as regards the members of the series present and their amplitudes and epochs. We may regard quality, then, as determined by the members of the harmonic series present and their amplitudes and epochs. It may, however, be stated here that certain experiments of Helmholtz appear to show that the epoch of the harmonics has not much effect on the quality.

Fourier's theorem can also be usefully applied to the disturbance of a source of sound under certain conditions. The nature of these conditions will be best realized by considering the case of a stretched string. It is shown, in O. A. § 55, how the vibrations of a string may be deduced from stationary waves. Let us here suppose that the string AB is displaced into the form AHB (Fig. 8). Then let us imagine it to form half a wave length of the extended train ZGAHBKC, on an indefinitely extended stretched string, the values of y at equal distances from A (or from B) being equal and opposite. Then we may suppose the vibrations of the string to be represented by the travelling of two trains in opposite directions each with velocity

$$\sqrt{\text{tension} \div \text{mass per unit length}}$$

each half the height of the train represented in Fig. 8. For the superposition of these trains will give a stationary wave between A and B. Now we may resolve these trains by Fourier's theorem into harmonics of wave lengths $\lambda, \frac{\lambda}{2}, \frac{\lambda}{3}, \dots$ etc., where $\lambda=2AB$ and the condition as to the values of y can be shown to require that the harmonics shall all have nodes, coinciding with the nodes of the fundamental curve. Since the velocity is the same for all disturbances they all travel at the same speed, and the two trains will always remain of the same form. If then we resolve AHBKC into harmonics by Fourier's theorem, we may follow the motion of the separate harmonics, and their superposition will give the form of the string at any instant. Further, the same harmonics with the same amplitude will always be present.

Fig. 8.

We see, then, that the conditions for the application of Fourier's theorem are equivalent to saying that all disturbances will travel along the system with the same velocity. In many vibrating systems this does not hold, and then Fourier's theorem is no longer an appropriate resolution. But where it is appropriate, the disturbance sent out into the air contains the same harmonic series as the source.

The question now arises whether the sensation produced by a periodic disturbance can be analysed in correspondence with this geometrical analysis. Using the term note for the sound produced by a periodic disturbance, there is no doubt that a well-trained ear can resolve a note into pure tones of frequencies equal to those of the fundamental and its harmonics. If, for instance, a note is struck and held down on a piano, a little practice enables us to hear both the octave and the twelfth with the fundamental, especially if we have previously directed our attention to these tones by sounding them. But the

harmonics are most readily heard if we fortify the ear by an air cavity with a natural period equal to that of the harmonic to be sought. The form used by **Resonators.** Helmholtz is a globe of thin brass with a large hole at one end of a diameter, at the other end of which the brass is drawn out into a short, narrow tube that can be put close to the ear. But a card-board tube closed at one end, with the open end near the ear, will often suffice, and it may be tuned by more or less covering up the open end. If the harmonic corresponding to the resonator is present its tone swells out loudly.

This resonance is a particular example of the general principle that a vibrating system will be set in vibration by any periodic force applied to it, and ultimately in the period of the force, its own natural vibrations gradually dying down. Vibrations thus excited are termed *Forced Vibrations*, and their amplitude is greater the more nearly the period of the applied force approaches that of the system when vibrating freely. The mathematical investigation of forced vibrations (Rayleigh, *Sound*, i. § 46) shows that, if there were no dissipation of energy, the vibration would increase indefinitely when the periods coincided. But there is always leakage of energy either through friction or through wave-emission, so that the vibration only increases up to the point at which the leakage of energy balances the energy put in by the applied force. Further, the greater the dissipation of energy the less is the prominence of the amplitude of vibration for exact coincidence over the amplitude when the periods are not quite the same, though it is still the greatest for coincidence.

According to Helmholtz, the ear probably contains within it a series of resonators, with small intervals between the periods of the successive members, while the series extends over the whole range of audible pitch. We need not here enter into the question of the structure constituting these resonators. Each of them is supposed to have its own natural frequency, and to be set into vibration when the ear receives a train of waves of that frequency. The vibration in some way arouses the sensation of the corresponding tone. But the same resonator will be appreciably though less affected by waves of frequency differing slightly from its own. Thus Helmholtz from certain observations (Rayleigh, *Sound*, ii. § 388) thought that if the intensity of response by a given resonator in the ear to its own tone is taken as 1, then its response to an equally loud tone a semitone different may be taken as about $\frac{1}{10}$. According to this theory, then, when a pure tone is received the auditory apparatus corresponding to that tone is most excited, but the apparatus on each side of it is also excited, though by a rapidly diminishing amount, as the interval increases. If the sensations corresponding to these neighbouring elements are thus aroused, we have no such perception as a pure tone, and what we regard as a pure tone is the mean of a group of sensations. The sensitiveness of the ear in judging of a given tone must then correspond to the accuracy with which it can judge of the mean.

Determinations of the pressure changes, or extent of excursion of the air, in sounding organ pipes have been made by Kundt (*Pogg. Ann.* cxxxiv. 1868, p. 163), Töpler and Boltzmann (*Pogg. Ann.* cxli., or Rayleigh, *Sound*, § 422a), and Mach (*Optisch-Akustischen Versuche*). Mach's method is perhaps the most direct. The pipe was fixed in a horizontal position, and along the top wall ran a platinum wire wetted with sulphuric acid. When the wire was heated by an electric current a fine line of vapour descended from each drop. The pipe was closed at the centre by a membrane which prevented a through draught, yet per-

mitted the vibrations, as it was at a node. The vapour line, therefore, merely vibrated to and fro when the pipe was sounded. The extent of vibration at different parts of the pipe was studied through a glass side wall, a stroboscopic method being used to get the position of the vapour line at a definite part of the vibration. Mach found an excursion of 0.4 cm. at the end of an open pipe 125 cm. long. The amplitude found by the other observers was of the same order.

Lord Rayleigh has made experiments by two different methods to determine the amplitude of vibration in waves only just audible (*Sound*, ii. § 384). It will be sufficient to indicate the second method. A fork of frequency 256 was used as the source. The energy of this fork with a given amplitude of vibration could be calculated from its dimensions and elasticity, and the amplitude was observed by measuring with a microscope the line into which the image of a starch grain on the prong was drawn by the vibration. The rate of loss of energy was calculated from the rate of dying down of the vibration. This rate of loss for each amplitude was determined (1), when the fork was vibrating alone, and (2) when a resonator was placed with its mouth under the free ends of the fork. The difference in loss in the two cases measured the energy given up to and sent out by the resonator as sound. The amplitude of the fork was observed when the sound just ceased to be audible at 27.4 metres away, and the rate of energy emission from the resonator was calculated to be $42.1 \frac{\text{ergs}}{\text{second}}$. Assuming this energy to be propagated in hemispherical waves, it is easy to find the quantity per second going through 1 sq. cm. at the distance of the listener, and thence from the energy in a wave, found above, to determine the amplitude. The result was an amplitude of 1.27×10^{-7} cm. Other forks gave results not very different. M. Wien (*Wied. Ann.* xxxvi. 1889, p. 834) by another method has obtained a smaller value still, though one of the same order. He used a globular resonator in which the pressure variations could be determined by a contrivance something like a delicate aneroid barometer. From the pressure changes the amplitude was known, and from Helmholtz's theory of the resonator the amplitude in the external exciting waves was calculated. All the results show that "the streams of energy required to influence the eye and ear are of the same order of magnitude."

The simple theory of the vibration of air in pipes, due to Bernoulli, practically assumes that a stationary wave is formed with a node at a closed end and a loop at an open end. But (as pointed out in O. A. § 85) the condition for a loop at an open end, that of no pressure variation, cannot be exactly fulfilled. This would require that the air outside should have no mass in order that it should at once move out and relieve the air at the end of the pipe from any excess of pressure, or at once move in and fill up any defect. There are variations, therefore, at the open end, and these are such that the loop may be regarded as situated a short distance outside the end of the pipe. It may be noted that in practice there is another reason for pressure variation at the end of the pipe. The stationary wave method regards the vibration in the pipe as due to a series of waves travelling to the end and being there reflected back down the pipe. But the reflection is not complete, for some of the energy comes out as waves; hence the direct and reflected trains are not quite equal, and cannot neutralize each other at the loop.

The position of the loop has not yet been calculated for an ordinary open pipe, but Lord Rayleigh has shown (*Sound*, ii. § 307), that for a cylindrical tube of radius R, provided with a flat extended flange, the loop may be re-

Vibrations of air in pipes.

Amplitude of vibration.

garded as about 0.82 R, in advance of the end. That is, the length of the pipe must be increased by 0.82 R before applying Bernouilli's theory. This is termed the end correction. Using this result Rayleigh found the correction for an unflanged open end by sounding two pipes nearly in unison, each provided with a flange, and counting the beats. Then the flange was removed from one and the beats were again counted. The change in virtual length by removal of the flange was thus found, and the open end correction for the unflanged pipe was 0.6 R. This correction has also been found by Blaikley by direct experiment (*Phil. Mag.* vii. 1879, p. 339). He used a tube of variable length and determined the length resounding to a given fork, (1) when the closed end was the first node, (2) when it was the second node. If these lengths are l_1 and l_2 , then $l_2 - l_1 = \frac{\lambda}{2}$ and $\frac{l_2 - l_1}{2} - l_1$ is the correction for the open end.

The mean value found was 0.576 R.

Helmholtz investigated the velocity of propagation of sound in pipes, taking into account the viscosity of the air (*Rayleigh, Sound*, ii. § 347), and Kirchhoff investigated it, taking into account both the viscosity and the heat communication between the air and the walls of the pipe (*Sound*, ii. § 350). Both obtained the value for the velocity

$$U \left(1 - \frac{C}{R\sqrt{2\pi N\rho}} \right),$$

where U is the velocity in free air, R is the radius of the pipe, N the frequency, and ρ the air density. C is a constant, equal to the coefficient of viscosity in Helmholtz's theory, but less simple in Kirchhoff's theory. Experiments on the velocity in pipes were carried out by Schneebeli (*Pogg. Ann.* cxxxvi. 1869, p. 296), and by Seebeck (*Pogg. Ann.* cxxxix. 1870, p. 104) which accorded with this result as far as R is concerned, but the diminution of velocity was found to be more nearly proportional to $N^{-\frac{3}{2}}$. Kundt also obtained results in general agreement with the formula (*Rayleigh, Sound*, ii. § 260). He used his dust-tube method (O. A. § 93).

Kundt's dust-tube may also be employed for the determination of the ratio of the specific heats of a gas or vapour. If U is the velocity of sound in a gas at pressure P with density ρ , and if waves of length λ and frequency N are propagated through it, then the distance between the dust-heaps is

$$d = \frac{\lambda}{2} = \frac{U}{2N} = \frac{1}{2N} \sqrt{\frac{\gamma P}{\rho}},$$

where γ is the ratio of the two specific heats. If d is measured for two gases in succession for the same frequency N, we have

$$\frac{\gamma_2}{\gamma_1} = \frac{\rho_2 P_1 d_2^2}{\rho_1 P_2 d_1^2},$$

where the suffixes denote the gases to which the quantities relate. If γ_1 is known this gives γ_2 . Kundt and Warburg applied the method to find γ for mercury vapour (*Pogg. Ann.* clvii. 1876, p. 356), using a double form of the apparatus in which there are two dust-tubes worked by the same sounding rod. This rod is supported at $\frac{1}{4}$ and $\frac{3}{4}$ of its length where it enters the two dust-tubes,

Fig. 9.

as represented diagrammatically in Fig. 9. It is stroked in the middle so as to excite its second mode of vibration. The method ensures that the two frequencies shall be exactly the same. In the mercury experiment the sounding rod was sealed into the dust-tube, which was exhausted of air, and contained only some mercury and some quartz dust to give the heaps. It was placed in a high temperature oven, where the mercury was evaporated. The second tube containing air was outside. When a known temperature was attained the sounder was excited, and d_2 and d_1 could be measured. From the temperature, P_2/ρ_2 was known, and

γ_2/γ_1 could then be found. Taking $\gamma_1 = 1.41$, γ_2 was determined to be 1.66. Rayleigh and Ramsay (*Phil. Trans.* A. 1895, part i. p. 187) also used a single dust-tube with a sounder to find γ for argon, and again the value was 1.66.

When a system is set vibrating and left to itself, vibration gradually dies away as the energy leaks either in the waves formed or through friction.

In order that the vibration may be maintained, a periodic force must be applied either to aid the internal restoring force on the return journey, or weaken it on the outgoing journey, or both. Thus if a dulcimer always receives a slight impulse in the direction of motion just about the lowest point, this is equivalent to an increase of the restoring force if received before passing through the lowest point, and to a decrease if received after that passage, and in either case it tends to maintain the swing. If the bob of the pendulum is iron, and if a coil is placed just below the centre of swing, then, if a current passes through the coil, while and only while the bob is moving towards it, the vibration is maintained. If the current is on while the bob is receding, the vibration is checked. If it is always on it only acts as if the value of gravity were increased, and does not help to maintain the vibration, but merely to shorten the period. In a common form of electrically maintained fork, the fork is set horizontal with its prongs in a vertical plane, and a small electromagnet is fixed between them. The circuit of the electromagnet is made and broken by the vibration of the fork in different ways—say, by a wire bridge attached to the lower prong which dips into and lifts out of two mercury cups. The mercury level is so adjusted that the circuit is just not made when the fork is at rest. When set vibrating contact lasts during some part of the outward and some part of the inward swing. But owing to the delay in making contact through the downward of air on the contact piece, and partly owing to delay in establishing full current through self-induction the attracting force does not rise at once to its full value in the outgoing journey, whereas in the return journey the mercury tends to follow up the contact piece, and full current continues up to the instant of break. Hence the attracting force does more work in the return journey than is done against it in the outgoing, and the balance is available to increase the vibration.

In the organ pipe—as in the common whistle—a sheet of air is forced through a narrow slit at the bottom of the embouchure and impinges against the top edge, which is made very sharp. The disturbance made at the commencement of the blowing will no doubt set the air in the pipe vibrating in its own natural period, just as any irregular air disturbance will set a suspended body swinging in its natural period, but we are to consider how the vibration is maintained when once set going. When the motion due to the vibration is up along the pipe from the embouchure, the air moves into the pipe from the outside, and carries the sheet-like stream in with it to the inside of the sharp edge. This stream does work on the air, aiding the motion. When the motion is reversed and the air moves out of the pipe at the embouchure, the sheet is deflected on to the outer side of the sharp edge, and no work is done against it by the air in the pipe. Hence the stream of air does work during half the vibration which is not abstracted during the other half, and so goes on increasing the motion until the supply of energy in blowing is equal to the loss by friction and sound.

The maintenance of the vibration of the air in the singing tube (described O. A. § 89) has been explained by Rayleigh (*Sound*, ii. § 322 h) as due to the way in which the heat is communicated to the vibrating air. When the air in a

Maintenance of vibration

Electrically maintained fork

Organ pipe

Singing tube

pipe open at both ends is vibrating in its simplest mode, the air is alternately closing into and out from the centre. During the quarter swing ending with greatest nodal pressure, the kinetic energy is changed to potential energy manifested in the increase of pressure. This becomes again kinetic in the second quarter swing, then in the third quarter it is changed to potential energy again, but now manifested in the decrease of pressure. In the last quarter it is again turned to the kinetic form. Now suppose that at the end of the first quarter swing, at the instant of greatest pressure, heat is suddenly given to the air. The pressure is further increased and the potential energy is also increased. There will be more kinetic energy formed in the return journey and the vibration tends to grow. But if the heat is given at the instant of greatest rarefaction, the increase of pressure lessens the difference from the undisturbed pressure, and lessens the potential energy, so that during the return less kinetic energy is formed and the vibration tends to die away. And what is true for the extreme points is true for the half periods of which they are the middle points; that is, heat given during the compression half aids the vibration, and during the extension half damps it. Now let us apply this to the singing tube. Let the gas jet tube be of somewhat less than half the length of the singing tube, and let the lower end of the jet tube be in a wider tube or cavity so that it may be regarded as an "open end." When the air in the singing tube is singing, it forces the gas in the jet tube to vibrate in the same period and in such phase that at the nozzle the pressure in both tubes shall be the same. The lower end of the jet tube, being open, is a loop, and the node may be regarded as in an imaginary prolongation of the jet tube above the nozzle. It is evident that the pressure condition will be fulfilled only if the motions in the two tubes are in the same direction at the same time, closing into and opening out from the nodes together. When the motion is upwards gas is emitted; when the motion is downwards it is checked. The gas enters in the half period from least to greatest pressure. But there is a slight delay in ignition, partly due to expulsion of incombustible gas drawn into the jet tube in the previous half period, so that the most copious supply of gas and heat is thrown into the quarter period just preceding greatest pressure, and the vibration is maintained. If the jet tube is somewhat longer than half the sounding tube there will be a node in it, and now the condition of equality of pressure requires opposite motions in the two at the nozzle, for their nodes are situated on opposite sides of that point. The heat communication is then chiefly in the quarter vibration just preceding greatest rarefaction, and the vibration is not maintained.

When a flame is just not flaring, any one of a certain range of notes sounded near it may make it flare while the note is sounding. This was first noticed by Leconte (*Phil. Mag.* xv. 1858, p. 235), and later by Barrett (*Phil. Mag.* xxxiii. 1867, p. 216). Barrett found that the best form of

Sensitive flames and jets.

burner for ordinary gas pressure might be made of glass tubing about $\frac{3}{8}$ inch in diameter contracted to an orifice $\frac{1}{16}$ inch in diameter, the orifice being nicked by a pair of scissors into a V-shape. The flame rises up from the burner in a long thin column, but when an appropriate note is sounded it suddenly drops down and thickens. Barrett further showed by using smoke jets that the flame is not essential. Tyndall (*Sound*, Lecture VI. § 7 *et seq.*) describes a number of beautiful experiments with jets at higher pressure than ordinary, say 10 inches of water, issuing from a pinhole steatite burner. The flame may be 16 inches high, and on receiving a suitably high sound it

suddenly drops down and roars. The sensitive point is at the orifice. Lord Rayleigh (*Sound*, ii. § 370), using as a source a "bird-call," a whistle of high frequency formed a series of stationary waves by reflection at a flat surface. Placing the sensitive frame at different parts of this train, he found that it was excited, not at the nodes where the pressure varied, but at the loops where the motion was the greatest and where there was little pressure change. In his *Sound* (ii. chapter xxi.) he has given a theory of the sensitiveness. When the velocity of the jet is gradually increased there is a certain range of velocity for which the jet is unstable, so that any deviation from the straight rush-out tends to increase as the jet moves up. If then the jet is just on the point of instability, and is subjected at its base to alternations of motion, the sinuosities impressed on the jet become larger and larger as it flows out, and the flame is as it were folded on itself. Another form of sensitive jet is very easily made by putting a piece of fine wire gauze 2 or 3 inches above a pinhole burner and igniting the gas above the gauze. On adjusting the gas so that it burns in a thin column, just not roaring, it is extraordinarily sensitive to some particular range of notes, going down and roaring when a note is sounded. If a tube be placed over such a flame it makes an excellent singing tube.

If a jet of water issues at an angle to the horizontal from a round pinhole orifice under a few inches pressure, it travels out as an apparently smooth cylinder for a short distance and then breaks up into drops which travel at different rates, collide, and scatter. But if a tuning-fork of appropriate frequency be set vibrating with its stalk in contact with the holder of the pipe from which the jet issues, the jet appears to go over in one continuous thread. Intermittent illumination, however, with frequency equal to that of the fork shows at once that the jet is really broken up into drops, one for each vibration, and that these move over in a steady procession. The cylindrical form of jet is unstable if its length is more than π times its diameter, and usually the irregular disturbances it receives at the orifice go on growing, and ultimately break it up irregularly into drops which go out at different rates. But, if quite regular disturbances are impressed on the jet at intervals of time which depend on the diameter and speed of out-flow (they must be somewhat more than π times its diameter apart), these disturbances go on growing and break the stream up into equal drops, which all move with the same velocity one after the other. An excellent account of these and other jets is given in *Boys' Soap Bubbles*, Lecture III.

Savart's liquid jets.

The formation of beats (as described in O. A. § 102) may be illustrated by considering the disturbance at any point due to two trains of waves of equal amplitude a and of nearly equal frequencies n_1, n_2 . If we measure the time from an instant at which the two are in the same phase the resultant disturbance is

Beats.

$$y = a \sin 2\pi n_1 t + a \sin 2\pi n_2 t$$

$$= 2a \cos \pi(n_1 - n_2)t \sin 2\pi \frac{n_1 + n_2}{2} t,$$

which may be regarded as a harmonic disturbance of frequency $(n_1 + n_2)/2$ but with amplitude $2a \cos \pi(n_1 - n_2)t$ slowly varying with the time. Taking the square of the amplitude to represent the intensity or loudness of the sound which would be heard by an ear at the point, this is

$$4a^2 \cos^2 \pi(n_1 - n_2)t$$

$$= 2a^2 \{1 + \cos 2\pi(n_1 - n_2)t\},$$

a value which ranges between 0 and $4a^2$ with frequency $n_1 - n_2$. The sound swells out and dies down $n_1 - n_2$ times per second, or there are $n_1 - n_2$ beats per second.

If, instead of considering one point in a succession of instants, we consider a succession of points along the line of propagation at the same instant, we evidently have waves of amplitude varying from $2a$ down to 0 , and then up to $2a$ again in distance $U/(n_1 - n_2)$. If the difference of frequency of the two tones is so great that the beats are not heard separately, and if the two sounds are of sufficient loudness, then a tone is heard of the same frequency, $n_1 - n_2$, as the beats. This tone was first discovered by Sorge in 1740, and independently a few years later by Tartini, after whom it is named. It may easily be heard when a double whistle with notes of different pitch is blown strongly, or when two gongs are loudly sounded close to the hearer. It is heard, too, when two notes on the harmonium are loudly sounded. Formerly, it was generally supposed that the Tartini tone was due to the beats themselves, that the mere variation in the amplitude was equivalent, as far as the ear is concerned, to a superposition on the two original tones of a smooth sine displacement of the same periodicity as that variation. This view has still some supporters, and among its recent advocates are Koenig and Hermann. But it is very difficult to suppose that the same sensation would be aroused by a truly periodic displacement represented by a smooth curve, and a displacement in which the period is only in the amplitude of the to-and-fro motion, and which is represented by a jagged curve. No explanation is given by the supposition; it is merely a statement which can hardly be accepted unless all other explanations fail.

Helmholtz has given a theory which certainly accounts for the production of a tone of the frequency of the beats, and for other tones all grouped under the name of combination tones. The only question is whether the intensity of the tones heard is accounted for by the theory. Combination tones may be produced in three ways:—(1) In the neighbourhood of the source; (2) in the receiving mechanism of the ear; (3) in the medium conveying the waves.

(1) We may illustrate the first method by taking a case discussed by Helmholtz (*Sensations of Tone*, App. xvi.) where the two sources are reeds or pipes blown from the same wind-chest. Let us suppose that with constant excess of pressure, p , in the wind-chest, the amplitude produced is proportional to the pressure, so that the two tones issuing may be represented by $pa \sin 2\pi n_1 t$ and $pb \sin 2\pi n_2 t$. Now as each source lets out the wind periodically it affects the pressure in the chest so that we cannot regard this as constant, but may take it as better represented by $p + \lambda a \sin(2\pi n_1 t + e) + \mu b \sin(2\pi n_2 t + f)$. Then the issuing disturbance will be

$$\begin{aligned} & \{p + \lambda a \sin(2\pi n_1 t + e) + \mu b \sin(2\pi n_2 t + f)\} \{a \sin 2\pi n_1 t + b \sin 2\pi n_2 t\} \\ &= pa \sin 2\pi n_1 t + pb \sin 2\pi n_2 t \\ &+ \frac{a^2 \lambda}{2} \cos e - \frac{a^2 \lambda}{2} \cos(4\pi n_1 t + e) \\ &+ \frac{b^2 \mu}{2} \cos f - \frac{b^2 \mu}{2} \cos(4\pi n_2 t + f) \\ &+ \frac{ab \lambda}{2} \cos \{2\pi(n_1 - n_2)t + e\} - \frac{a \lambda b}{2} \cos \{2\pi(n_1 + n_2)t + e\} \\ &+ \frac{ab \mu}{2} \cos \{2\pi(n_1 - n_2)t - f\} - \frac{a b \mu}{2} \cos \{2\pi(n_1 + n_2)t + f\} \quad (1) \end{aligned}$$

Thus, accompanying the two original pure tones there are (1) the octave of each; (2) a tone of frequency $(n_1 - n_2)$; (3) a tone of frequency $(n_1 + n_2)$. The second is termed by Helmholtz the *difference tone*, and the third the *summation tone*. The amplitudes of these tones are proportional to the products of a and b multiplied by λ or μ . These combination tones will in turn react on the pressure and produce new combination tones with the original tones, or with each other, and such tones may be termed of the second, third, etc. order. It is evident that we may have tones of frequency

$$hn_1 \quad kn_2 \quad hn_1 - kn_2 \quad hn_1 + kn_2,$$

where h and k are any integers. But inasmuch as the successive orders are proportional to $\lambda^2 \lambda^3$, or $\mu^2 \mu^3$, and λ and μ are small, they are of rapidly decreasing importance, and it is not certain that any beyond those in equation (1) correspond to our

actual sensations. The combination tones thus produced in the source should have a physical existence in the air, and the amplitudes of those represented in (1) should be of the same order. The conditions assumed in this investigation are probably nearly realized in a harmonium and in a double siren of the form used by Helmholtz (O. A. § 51), and in these cases there can be no doubt that actual objective tones are produced, for they may be detected by the aid of resonators of the frequency of the tone sought for. If the tones had no existence outside the ear then resonators would not increase their loudness. There is not much difficulty in detecting the difference tone by a resonator if it is held, say, close to the reeds of a harmonium, and Helmholtz succeeded in detecting the summation tone by the aid of a resonator. Further, Rücker and Edser, using a siren as source, have succeeded in making a fork of the appropriate pitch respond to both difference and summation tones (*Phil. Mag.* xxxix. 1896, p. 341). But there is no doubt that it is very difficult to detect the summation tone by the ear, and many workers have doubted the possibility, notwithstanding the evidence of such an observer as Helmholtz. Probably the fact noted by Mayer (*Phil. Mag.* ii. 1878, p. 500, or Rayleigh, *Sound*, § 386) that sounds of considerable intensity when heard by themselves are liable to be completely obliterated by graver sounds of sufficient force goes far to explain this, for the summation tones are of course always accompanied by such graver sounds.

(2) The second mode of production of combination tones by the mechanism of the receiver is discussed by Helmholtz (*Sensations of Tone*, App. XII.) and Rayleigh (*Sound*, § 68). It depends on the restoring force due to the displacement of the receiver not being accurately proportional to the displacement. This want of proportionality will have a periodicity, that of the impinging waves, and so will produce vibrations just as does the variation of pressure in the case last investigated. We may see how this occurs by supposing that the restoring force of the receiving mechanism is represented by

$$\lambda x + \mu x^2,$$

where x is the displacement and μx^2 is very small. Let an external force F act on the system, and for simplicity suppose its period is so great compared with that of the mechanism that we may take it as practically in equilibrium with the restoring force. Then

$$F = \lambda x + \mu x^2.$$

Now μx^2 is very small compared with λx , so that x is nearly equal to F/λ , and as an approximation,

$$F = \lambda x + \frac{\mu F^2}{\lambda^2}$$

or

$$x = \frac{F}{\lambda} - \mu \frac{F^2}{\lambda^3}.$$

Suppose now that $F = a \sin 2\pi n_1 t + b \sin 2\pi n_2 t$, the second term will evidently produce a series of combination tones of periodicities $2n_1, 2n_2, n_1 - n_2$, and $n_1 + n_2$, as in the first method. There can be no doubt that the ear is an unsymmetrical vibrator, and that it makes combination tones, in some such way as is here indicated, out of two pure tones. Probably in most cases the combination tones which we hear are thus made, and possibly, too, the tones detected by Koenig, and by him named "beat-tones." He found that if two tones of frequencies p and q are sounded, and if q lies between Np and $(N+1)p$, then a tone of frequency either $(N+1)p - q$, or of frequency $q - Np$, is heard. The difficulty in Helmholtz's theory is to account for the audibility of such beat tones when they are of a higher order than the first. Rücker and Edser quite failed to detect their external existence, so that apparently they are not produced in the source. If we are to assume that the tones received by the ear are pure and free from partials, the loudness of the beat-tones would appear to show that Helmholtz's theory is not a complete account.

(3) The third mode of production of combination tones, the production in the medium itself, follows from the varying velocity of different parts of the wave, as investigated at the beginning of this article. It is easily shown that after a time we shall have to superpose on the original displacement a displacement proportional to the square of the particle velocity, and this will introduce just the same set of combination tones. But probably in practice there is not a sufficient interval between source and hearer for these tones to grow into any importance, and they can at most be only a small addition to those formed in the source or the ear.

AUTHORITIES.—LORD RAYLEIGH, *Sound*, 2nd ed. London, 1894, is the standard treatise on the phenomena of Acoustics; the last chapter, on "Facts and Theories of Audition," is a most valuable summary of the present state of knowledge of audition and the different theories held.—HELMHOLTZ, *Sensations of Tone*, 2nd Eng. ed. London, 1885, deals more with the physiological aspect.—SEDLAY TAYLOR, *Sound and Music*, London, 1873, is a general

account of Helmholtz's Theory of Consonance and Dissonance (briefly stated in O. A. § 106, but not discussed in this supplement).—POYNTING and THOMSON, *Sound*, London, 1899, is an elementary mathematical account of the phenomena of Acoustics. (J. H. P.*)

Acqui, a town and episcopal see of the province of Alessandria, Piedmont, Italy, 21 miles S.S.W. from Alessandria by rail. The castle of the Palæologi is now converted into a prison. Here is a technical school. Its sulphur baths attract annually about 4000 visitors. Population (1901), 13,786.

Acra (Arab. *Ākka*), a survival of the Biblical *Acco*, and ancient *Ake*, the chief town of a Palestine sanjak which includes Haifa, Nazareth, and Tiberias. From its commanding position on the sea-shore of a broad fertile plain over which the coast road from Syria to Egypt has always passed, and whence there is easy access to the rich lands of Galilee and the Trans-Jordanic countries, it has been called "the Key of Palestine," and its history is principally that of its many sieges. It was occupied in turn by Assyrians, Babylonians, Persians, and Greeks, but never by the Hebrews, and was assigned on the division of Alexander's kingdom to Ptolemy Soter, after whom it was called *Ptolemais*. One of its mediæval names, *Acon*, has been preserved in that of the church of St Nicholas Acons, in Lombard Street, London. It exports wheat, maize, olive oil, cotton, &c., but the trade is gradually passing to Haifa, where there is a safer roadstead. The town will be connected by a branch line with the Haifa-Damascus railway now being constructed. Population, 11,000 (Moslems, 8000; Christians, Jews, and others, 3000).

Actinozoa. See ANTHOZOA.

Acton, a parish and urban district (coextensive) in the suburbs of London, in the Ealing parliamentary division of Middlesex, about 7 miles W. of St Paul's, with three railway stations. Many distinguished persons have lived there, among them Richard Baxter, Sir Matthew Hale, Henry Fielding, and Lindley the botanist. A recreation ground of 21 acres was opened in 1887, and there are a cottage hospital, a free library (1900), and a Thomas Aske girls' school (1901). Area, 2305 acres. Population (1881), 17,110; (1891), 24,206; (1901), 37,744.

Acton, John Emerich Edward Dalberg Acton, 1st BARON (1834—), son of Sir Ferdinand Acton, Bart., was born at Naples, 10th January 1834. His mother, who after her husband's death in 1837 married Earl Granville, was the daughter of the duke of Dalberg, which caused Lord Acton, after studying under Cardinal Wiseman at the Roman Catholic college at Oscott, to receive the most valuable part of his education in Bavaria. Under the inspiration of Döllinger, in whose house he lived for a considerable time, he imbibed not only that love of history, but that disposition to treat history as a science in a thoroughly impartial spirit, and to render a profound investigation of canon and of international law auxiliary to historical research, which have ever since distinguished him. Such a spirit must be one of especial hostility to ultramontane pretensions; and Lord Acton, although a sincere Catholic, made it for a time his especial mission to combat these in the *Home and Foreign Review*, which he conducted from 1862 to 1864 with a vigour insuring its condemnation and virtual suppression by the Roman Catholic hierarchy. Nothing daunted, Lord Acton and his friends acquired the *North British Review*, hitherto an organ of the Free Church of Scotland, and carried it on actively for several years in the interest of a high-class Liberalism both in temporal and in ecclesiastical matters. Lord Acton contributed several valuable

articles, and in 1870 proceeded to Rome to take such part as was possible to a layman in opposing the promulgation of the dogma of papal infallibility. He was active as a writer under his own name and as an inspirer of the writings of others, but the calamity so much dreaded by Liberal Catholics was not to be averted. The Old Catholic separation followed, but Lord Acton held aloof. He had been raised to the peerage in 1869, but his great knowledge and breadth of view have been too little enlisted in the service of the House of Lords. In 1874, however, he came forward conspicuously as a supporter of Mr Gladstone in the controversy on "Vaticanism," pointing out in a series of letters to the *Times* various actions and characteristics of individual popes by no means easy to reconcile with the doctrine of papal infallibility. For many years little came from his pen except an article on the divorce of Henry VIII. in the *Quarterly Review* for 1877, and an essay on modern German historians, contributed to the first number of the *English Historical Review* in 1886. In 1895, however, his acceptance of the Regius Professorship of Modern History at Cambridge, vacant by the death of Sir John Seeley, drew from him an inaugural lecture on "The Study of History," with notes displaying a vast erudition, by no means merely historical. Lord Acton has since continued to lecture regularly, and, at the instance of the university, undertook the editorship of a great modern history by various writers from the middle of the 15th century to the present day. Lord Acton is an Honorary Fellow of All Souls' college, Oxford, and was a lord-in-waiting from 1892 to 1895.

Acts of the Apostles.—In this article we shall deal with such additions to our knowledge as have been made since 1875, when the article in the ninth edition of this work was published.

Text.—The apparatus criticus of Acts has grown considerably of recent years; yet mainly in one direction, that of the so-called "Western" text. This term, which our growing knowledge, especially of the Syriac and other Eastern versions, is rendering more and more unsatisfactory, stands for a text which used to be connected almost exclusively with the "eccentric" *Codex Bezae*. But it is now recognized to have been very widespread, both in east and west, for some 200 years or more from about the middle of the 2nd century. The process, however, of sifting out the readings of all our present witnesses—MSS., versions, fathers—has not yet gone far enough to yield any sure or final result as to the history of this text, so as to show what in its extant forms is primary, secondary, and so on. Beginnings have been made towards grouping our authorities; but the work must go on much further before a solid basis for the reconstruction of its primitive form can be said to exist. The attempts so far made at such a reconstruction, as by Blass (1895, 1897) and Hilgenfeld (1899), are quite arbitrary. And the like must be said of the most recent contribution to the problem, that of August Pott,¹ though he has helped to define one condition of success—the classification of the strata in "Western" texts—and has taken some steps in the right direction, in connexion with the complex phenomena of one witness, the Harklean Syriac.

Assuming, however, that the original form of the "Western" text had been reached, the question of its historical value, *i.e.*, its relation to the original text of Acts, yet remains. On this point the highest claims have recently been made by Blass. Ever since 1894 he has held that both the "Western" text of Acts (which he styles the β text) and its rival, the text of the great uncials

¹ *Der abendländische Text der Apostelgeschichte u. die Wirkquelle.* Leipzig, 1900.

(which he styles the α text), are due to the author's own hand. Further, that the former is the more original of the two, being related to the latter as fuller first draft to severely pruned copy. But even in its latest form, that " β stands nearer the *Grundschrift* than α , but yet is, like α , a copy from it," the theory is really untenable. In sober contrast to Blass' sweeping theory stand the views of Prof. W. M. Ramsay. Already in *The Church in the Roman Empire* (1893) he held that the *Codex Bezae* rested on a recension made in Asia Minor (somewhere between Ephesus and S. Galatia), not later than about the middle of the 2nd century. Though "some at least of the alterations in *Codex Bezae* arose through a gradual process, and not through the action of an individual reviser," the revision in question was the work of a single reviser, who in his changes and additions expressed the local interpretation put upon Acts in his own time. His aim, in suiting the text to the views of his day, was partly to make it more intelligible to the public, and partly to make it more complete. To this end he "added some touches where surviving tradition seemed to contain trustworthy additional particulars," such as the statement that Paul taught in the lecture-room of Tyrannus "from the fifth to the tenth hour." In his later work, on *St Paul the Traveller and the Roman Citizen* (1895), Ramsay's views gain both in precision and in breadth. The gain lies chiefly in seeing beyond the Bezan text to the "Western" text as a whole. But when he writes that, "wherever the Bezan text is confirmed by old versions and by certain Greek MSS., it seems to me to deserve very earnest consideration, as at least pointing in the direction of an original reading subjected to widespread corruption," he goes beyond the mark. Such agreement need not mean more than that the reading is a gloss belonging to the "Western" text, as it arose under conditions which Ramsay himself excellently describes.

On the whole, then, the text of Acts as printed by Westcott and Hort, on the basis of the earliest MSS. ($\alpha\beta$), seems as near the autograph as that in any other part of the New Testament; whereas the "Western" text, even in its earliest traceable forms, is secondary. This does not mean that it has no historical value of its own. It may well contain some true supplements to the original text, derived from local tradition or happy inference; certain of these may even date from the end of the 1st century, and the larger part of them are probably not later than the middle of the 2nd. But its value lies mainly in the light cast on the ecclesiastical tradition in certain quarters during the epoch in question. The nature of the readings themselves, and the distribution of the witness for them, alike point to a process involving several stages and several originating centres of diffusion. The classification of groups of "Western" witnesses has already begun. When completed, it will cast light, not only on the origin and growth of this type of text, but also on the exact value of the remaining witnesses to the original text of Acts.

Plan and Object of Acts.—Here the Tübingen school did its chief work in putting the needful question, not in returning the correct answer. Their answer could not be correct, because, as Ritschl shows, their premises were wrong. Still the attitude created by the Tübingen theory largely persists as a biasing element in much that is written about Acts. On the whole, however, there is a disposition to look at the book more objectively, and to follow up the hints as to its aim given by the author in his opening verses. Thus (1) his second narrative is the natural sequel to his first. As the earlier one set forth in orderly sequence ($\kappa\alpha\theta\epsilon\acute{\xi}\eta\varsigma$) the providential stages, by which Jesus was led, "in the power of the Spirit," to begin the establishment of the consummated Kingdom of

God; so the later work aims at setting forth on similar principles its extension by means of His chosen representatives or apostles. This involves emphasis on the identity of the power, *i.e.*, divine and not merely human power, expressed in the great series of facts from first to last, and so upon (2) the Holy Spirit, as directing and energizing throughout the whole struggle with the powers of evil to be overcome in either ministry, of Master or disciples. But (3) the continuity is more than similarity of activity, resting on the same divine energy. The working of the energy in the disciples is conditioned by the continued life and volition of their Master at His Father's right hand in heaven. The living link between Master and disciples is the Holy Spirit, "the Spirit of Jesus." Hence the pains taken to exhibit afresh (i. 2, 4 f. 8, ii. 1 ff., *cf.* Luke xxiv. 49) the fact of such spiritual solidarity, whereby their activity means His continued action in the world. And (4) the scope of this action is nothing less than humanity as gathered within the Roman empire. It was foreordained that Messiah's witnesses should be borne by divine power through all obstacles and to ever-widening circles, until they reached and occupied Rome itself for the God of Israel—now manifest (as foretold by Israel's own prophets) as the one God of the one race of mankind. (5) Further, as we gather from the parallel account in Luke xxiv. 46-48, the divinely appointed method of victory is through suffering (Acts xiv. 22). This thought explains the large space devoted to the tribulations of the witnesses, and their constancy amid them, after the type and sample of their victorious Lord. It forms one side of the virtual *apologia* for the absence of that outward prosperity in which the pagan mind was apt to see the token of divine approval. Another side is the recurring exhibition of the fact that these witnesses were persecuted only by those whose action should create no bias against the persecuted. Their foes were chiefly Jews, whose opposition was due partly to a stiff-necked disinclination to bow to the wider reading of their own religion—to which the Holy Spirit had from of old been pointing—and partly to jealousy of those who, by preaching the wider Messianic Evangel, were winning over the Gentiles, and particularly proselytes, in such great numbers.

Such, then, seem to be our author's main *motifs*. They make up an account fairly adequate to the manifoldness of the book; and yet they all run up into one central idea, *viz.*, the divine character of the Christian religion, as evinced by the manner of its extension in the empire. This view has the merit of giving the book a practical religious aim—a *sine quod non* to any theory of an early Christian writing. Though addressed to men of pagan birth in the first instance, it is to them as inquirers or even recent converts, such as "Theophilus," that the appeal is made. In spite of all difficulties, this religion is worthy of personal belief and acceptance. Such is the moral of our author's work. Yet among the conditioning features of the occasion, which impressed him with the need of such an appeal, was doubtless the existence of persecution now actually carried out by the Roman authorities, sometimes perhaps of their own motion. To meet this special perplexity our author holds up the picture of early days, when the great protagonists of the Gospel constantly enjoyed protection at the hands of Roman justice. It is implied that the present distress was but a passing phase, resting on some misunderstanding; meantime, the spectacle of apostolic constancy should yield strong consolation to the tried.

From this standpoint Acts no longer seems to end abruptly. Whether as exhibiting marvellous divine leading and aid, or as recording the impartial and even kindly attitude of the Roman state towards the Christians, the

writer has reached a climax. "He wished," as Harnack well remarks, "to point out the might of the Holy Spirit in the apostles, Christ's witnesses; and to show how this might carried the Gospel from Jerusalem to Rome and gained for it entrance into the pagan world, whilst the Jews in growing degree incurred rejection. In keeping with this, verses 26-28 of chapter xxviii. are the solemn closing verses of the work. But verses 30, 31 are an appended observation." So far, so good; but objection may be taken when Harnack goes on to say that this observation does not admit of explanation from the plan of the work, "but rather from the almost independent interest which, not so much the life of Paul, as the marvellous manner of the realization of Paul's journey to Rome, had incidentally acquired for the author." To many it will seem that the writer is ending up most fitly on one of his keynotes, in that he leaves Paul preaching in Rome itself, "unmolested." The full force of this is missed by those who, while rejecting the idea that the author had in reserve enough Pauline history to furnish another work, yet hold that Paul was freed from the imprisonment amid which Acts leaves him.¹ But for those, on the other hand, who see in the writer's own words in xx. 38, uncontradicted by anything in the sequel, a broad hint that Paul never saw his Ephesian friends again, the natural view is open that the sequel to the two years' preaching was too notorious to call for explicit record. Nor would such silence touching Paul's speedy martyrdom be disingenuous, any more than on the theory that martyrdom overtook him several years later. Our author would view Paul's death as a mere exception to the rule of Roman policy heretofore illustrated, due to the influence of a sort of madman, such as Nero was naturally held to be in the latter part of his reign. Not even by the Roman authorities were some of his acts regarded as precedents; and so our author could honestly refrain from recording what he viewed as a mere freak of Neronian caprice, especially as it would be already known to his contemporaries. Such silence would be the more natural if he were writing in Rome, a conclusion to which certain things are often thought to point.

Date.—External evidence now points to the existence of Acts at least as early as the opening years of the 2nd century. As evidence for the Third Gospel holds almost equally for Acts, its existence in Marcion's day (120-140) is now assured. Further, the traces of it in Polycarp² and Ignatius,³ when taken together, are highly probable. And what is still more important, it is probable that Acts was already known in Rome by c. A.D. 96. For it is widely admitted that the resemblance of Acts xiii. 22, and 1 Clem. xviii. 1, in features not found in the Psalm (lxxxix. 20) quoted by each, cannot be accidental.

<p>Acts xiii. 22. ἤγειρεν τὸν Δαυεὶδ . . . ὃ καὶ εἶπεν μαρτυρήσας, Εἶρον Δαυεὶδ τὸν τοῦ Ἰησοῦαι, ἀνδρα κατὰ τὴν καρδίαν μου [ἄνδρα κ.τ.λ. from 1 Sam. xiii. 14, ἀνθρώπου κ.τ.λ.].</p>	<p>1 Clem. xviii. 1. Τί δὲ εἶπωμεν ἐπὶ τῷ μαρμαρτημένῳ Δαυεὶδ; πρὸς ὃν εἶπεν ὁ θεός, Εἶρον ἀνδρα κατὰ τὴν καρδίαν μου, Δαυεὶδ τὸν τοῦ Ἰησοῦαι, ἐν ἐλέει αἰωνίου ἔχρισα αὐτόν.</p>
---	---

Here the Greek Bible has simply Εἶρον Δαυεὶδ τὸν δοῦλόν μου. Nor should the reference in either case to David as a man witnessed to by God, be overlooked, tending as it does to exclude the idea that the likeness

between the passages is due to some third source. The dependence seems clearly to be on the side of 1 Clement, especially in view of possible echoes of Acts xx. 35, which it contains in three distinct places (ii. 1, xiii. 1, xvi. 7, cf. Polyc. ii. 3). There is, then, high probability that Acts was current in Antioch and Smyrna not later than c. A.D. 115, and in Rome as early as c. A.D. 96.

With this view internal evidence agrees. In spite of Blass' advocacy of a date prior to A.D. 70, the bulk of critical opinion puts this theory firmly aside. Thus the prologue to the Gospel of which Acts is the sequel, already implies the dying out of the generation of eye-witnesses as a body. Of recent years, too, the relations of Church and Empire have been brought to bear, especially by Ramsay. And his dating, A.D. 81 or soon after, fits in with a strong consensus of critical opinion both in England and abroad—Harnack, for instance, placing Acts between 80 and 93, while Zahn prefers 75 to 80. So that A.D. 80 may be taken as a fair average date, while any year between it and 71 is open. Of the reasons for a date in one of the earlier decades of the second century, as argued by the Tübingen school and its heirs, several are now really untenable. Among these are the supposed traces of 2nd-century gnosticism and "hierarchical" ideas of organization; but especially the argument from the relation of the Roman state to the Christians, which Ramsay has completely reversed and turned into proof of an origin prior to Pliny's correspondence with Trajan on the subject. Another fact, now generally admitted, renders a 2nd-century date yet more incredible; and that is, the failure of a writer devoted to Paul's memory to make palpable use of his Epistles. Instead of this he writes in a fashion that seems to traverse certain facts recorded in them. If, indeed, it were proved that Acts uses the later works of Josephus, we should have to place the book about A.D. 100. But this is far from being the case, a critic like Harnack decisively rejecting the alleged dependence.

Sources.—So far from the recognition of a plan in Acts being in itself inimical to a serious quest after the materials used in its composition, one may say that it points the way thereto, while it keeps the literary analysis within scientific limits. Thus the more one realizes the theological standpoint of the mind pervading the book as a whole, the more one feels that the speeches in the first part of Acts—and indeed elsewhere, too—are not "free compositions" of our author, the outcome of dramatic idealization such as ancient historians like Thucydides or Polybius allowed themselves. The Christology, for instance, of the early Petrine speeches is such as a Gentile Christian writing c. 80 A.D. simply could not have imagined, even had the idea of adopting Judæo-Christian categories been present to his mind. Thus we are forced to assume the use of a certain amount of early Judæo-Christian material, analogous to that implied also in the special parts of the Third Gospel. One critic, at least, Paul Feine (*Eine vorkanonische Ueberlieferung des Lukas*, 1891), suggests that a single document explains this material in both works, as far as Acts xii.; while others maintain that more than one such source underlies Acts i.-xii., or even i.-xv. (*e.g.*, a source embodying the traditions of the largely Gentile Church of Antioch). Yet if our author was an Antiochene and a careful inquirer (Luke i. 3), this may explain all. It cannot, indeed, be said that definite results have here been attained as yet. But the study is a new one, and the resources of analysis, the linguistic in particular, are by no means exhausted. One important analogy for the way in which one author may be supposed to have handled his sources exists; and that is the manner in which he uses Mark's narrative in compiling his own Gospel.

¹ Unless we arbitrarily separate (in the face of the ancient Latin version) ἐπὶ τὸ τέρας τῆς δόσεως ἐλθῶν, from καὶ μαρτυρήσας ἐπὶ τῶν ἡγεμόνων οὕτως ἀπηλλάγη τοῦ κόσμου, 1 Clement v. 7 gives no support to this idea; while the next chapter seems clearly to put Paul's death not later than the Neronian persecution of A.D. 64.

² Polyc. ad Philipp. i. 2, Acts ii. 24; ii. 1, Acts x. 42; ii. 3, Acts xx. 35; vi. 3, Acts vii. 52.

³ Ign. ad Magn. v. 1, Acts i. 25; ad Smyrn. iii. 3, Acts x. 41.

Guided by such an objective criterion, and safeguarded by growing insight into the author's plastic aim, we need not despair of reaching large agreement as to the main scope of the sources lying behind the first half of Acts.

In the second or strictly Pauline half we are confronted by the so-called "we" passages. Of these two main theories are possible; that which sees in them traces of an earlier document—whether entries in a travel-diary, or a more or less consecutive narrative written later; and that which would regard the "we" as due to the author's breaking instinctively into the first person plural at those points in the history at which he himself had been present. On the former hypothesis, it is still in debate whether the "we" document does or does not lie behind more of the narrative than is definitely indicated by the formula in question (*e.g.*, cc. xiii.-xv., xxi. 19-xxvi.).

Authorship.—Was the author of the "we" passages, in any form, also the author of Acts as it now stands? And if so, was that author's name Luke, as ecclesiastical tradition has steadily affirmed from the time when its voice first reaches us? Few deny that Luke, *i.e.*, Paul's companion of that name, was the author of the "we" passages. The tradition connecting him with Acts is too early and unanimous to be mistaken, especially seeing that his name was not prominent enough to account for such an ascription by "spontaneous generation." Hence those who would see in the "we" passages traces of an earlier travel-document written by Timothy or Silas, seem bound in a special degree to make Luke the author of Acts as a whole. In this case, however, they have yet to explain how so skilled a writer, one elsewhere master of his sources as to literary form, could leave these sections couched in the first person of the eye-witness. And it may fairly be said that, if the weight of expert opinion is against the theory of literary negligence, it inclines also against the theory of pious fraud—the retention of the first person with intent to deceive. The net result is, that unity of authorship between the "we" passages and the rest of Acts seems the one tenable view; and this involves the Lucan authorship of both.¹ As to such historical difficulties in Acts as at present perplex the student of the Apostolic age, one must remember in most cases the possibilities of mistake intervening between the facts and the accounts reaching its author at second or even third hand. Yet it must be strongly emphasized that recent historical research at the hands of experts in classical antiquity has tended steadily to verify such parts of the narrative as it can test. That is no new result; but it has come to light in greater degree of recent years, and notably during the last decade. The proofs of our author's trustworthiness extend also to the theological sphere. What was said above of the Christology of the Petrine speeches, applies also to the whole conception of Messianic salvation, the eschatology, the idea of Jesus as equipped by the Holy Spirit for His Messianic work, found in these speeches, as also to titles like "Jesus the Nazarene" and "the Righteous One" both in and beyond the Petrine speeches. These and other cases in which we are led to discern Judæan witness behind Acts, do not indeed give to such witness the value of shorthand notes or even of abstracts based thereon. But they do support the theory that our author meant to give an unvarnished account of such words and deeds as had come to his knowledge. The perspective of the whole is no doubt his own; and as his witnesses probably furnished but few hints for a con-

tinuous historical narrative, this perspective, especially in things chronological, may sometimes be faulty. Yet when one remembers that by 80 A.D. it must have been a matter of small interest by what tentative stages the Messianic salvation first extended to the Gentiles, it is surely surprising that Acts enters into such detail on the subject, and is not content with a summary account of the matter such as the mere "logic" of the subject would naturally suggest. In any case the very difference of the perspective of Acts and of Galatians, in recording the same epochs in Paul's history, argues such an independence in the former as is compatible, in the case of an admirer of the apostle, only with an early date, when as yet Galatians might easily be unknown beyond the district to which it was addressed.²

Quellenkritik, then, a distinctive feature of recent research upon Acts, is a solvent of many difficulties in the way of treating Acts as an honest narrative by a companion of Paul. It will account, for instance, for such discrepancies as lie on the surface of the three accounts of Saul's conversion; while the fidelity with which our author uses his materials is shown by his not assimilating the accounts in Paul's speeches to the earlier narrative in chapter ix. In addition to *Quellenkritik*, we may also count among recent gains a juster method of judging such a book. For among the results of the Tübingen criticism was what Dr Sanday calls "an unreal and artificial standard, the standard of the 19th century rather than the 1st, of Germany rather than Palestine [may we not add Antioch or Rome?], of the lamp and the study rather than of active life." In the recovery of a more real standard, we owe much to men like Mommsen, Ramsay, and Blass, trained amid other methods and traditions than those which had brought the constructive study of Acts almost to a deadlock.

LITERATURE.—It would take too much space to give an account of the extensive and varied literature that gathered round Acts during the last quarter of the 19th century. It may be found in two recent and representative commentaries, *viz.*, Wendt's last edition of Meyer (1899), and that by R. J. Knowling in *The Expositor's Greek Testament*, vol. ii. 1900. (J. V. B.)

Adabazár, an important commercial town in Asia Minor, situated on the old military road from Constantinople to the east, and $5\frac{1}{2}$ miles distant from a station of the same name on the Anatolian railway. It was founded in 1540 and enlarged in 1608 by the settlement in it of an Armenian colony. There are silk and linen industries, and an export of tobacco, walnut-wood, cocoons, and vegetables for the Constantinople market. Imports are valued at £80,000, and exports at £480,000. Population, 18,000 (Moslems, 10,000; Christians, 8000).

Adalia, or **ANTALIA**, classical *Attaleia*, mediæval *Satalia*, the chief town and seaport of a sanjak of the Konia vilâyet in Asia Minor. It is situated at a re-entering angle, in a flat limestone terrace which terminates seaward in a cliff about 120 feet high, and had an inner and outer harbour. The town lies partly within and partly without the old walls, in which may still be seen the Perga gate, built by Hadrian, a tower erected by the Empress Julia, and many Greek and Latin inscriptions. There are several mosques and medresses (or schools) built by the Seljûk sultans of Rûm, and a few remains of Roman and Byzantine buildings.

Attaleia was founded, 159-138 B.C., to facilitate trade between the Pergamene kingdom and Syria and Egypt. Under the Romans it was an important town, connected by highways with Laodicea

¹ This accords excellently with the reference in Col. iv. 14 to Luke as a physician. For a good account of the argument from the medical language of Acts, see Knowling, *Expositor's Greek Testament*, vol. ii. 911.

² Nor should one forget the numerous but subtle agreements between Acts and Galatians which Ramsay has shown to be involved in the now victorious "South Galatian" theory, that sees in St Paul's "Galatians" the members of the churches whose foundation is described in Acts xiii. xiv.

and Pisidian Antioch, and the centre of a large sea-borne trade. It became the metropolis of Pamphylia, and in 1148 it gave timely shelter to the harassed troops that Louis VII. of France was leading to Palestine. Afterwards it passed to the Seljûk Turks, 1206; to the Venetians, 1307; to the Mongols, the Genoese, and finally to the Osmanli Sultan Murad II. (1421-51). Adalia has lost much of its trade since the opening of railways from Smyrna to the interior, but it still exports cereals, timber, valonea, liquorice root, and cotton; the exports in 1899 were valued at £152,156, the imports at £120,073. It is the seat of a British vice-consulate. Population, 30,000 (Moslems, 24,000; Christians, many apparently of Jewish origin, 6000).

Adamawa, a country of West Africa, now divided between the British colony of Nigeria (which includes the chief town, Yola) and the German colony of Cameroon. Recent estimates place the height of the granite range of Alantika, the loftiest point in the country, at only 6000 feet. The pagan negro tribes have been dominated by the Mahomedan Fullas, so widely spread over West and Central Africa, for about four centuries. There are also in the country to-day large numbers of Haussas, who continue to push southwards as traders, as well as Arabs and Kanuri. The Emir of the state of Yola formerly claimed rights of suzerainty over the whole of Adamawa, but the country now consists of a number of separate sultanates which are gradually being brought under the influence of the British and Germans. The town of Garua on the Upper Benue is one of the principal trade centres in the north, and that of Yoko one of the principal in the south. After Barth, the first traveller to penetrate Adamawa was the German, E. R. Flegel (1882), but the country has since been traversed by many expeditions, especially that of Uechtritz and Passarge (1893-94). (See especially *PASSARGE. Adamawa. Berlin, 1895.*)

Adams, a town in Berkshire county, in the north-western part of Massachusetts, U.S.A., having an area of 23 square miles. It includes a portion of the valley of Hoosac river, extending to the Hoosac range on the east, and on the west to Greylock mountain, the highest point in the state, having an altitude of 3505 feet. The valley portion is level and contains several villages, the largest of which bears the same name as the town. Adams village is on a branch of the Boston and Albany railroad, is irregularly laid out, and has an altitude above sea of 798 feet. The town was incorporated in 1778. The population in 1880 was 5591; in 1890 it was 9213, and in 1900 it was 11,134.

Adams, Charles Francis (1807-1886), American diplomatist, son of John Quincy Adams, and grandson of John Adams, was born in Boston on the 18th of August 1807. His father, having been appointed minister to Russia, took him to St Petersburg, where he acquired a perfect familiarity with French, learning it as his native tongue. After eight years spent in Russia and England, he attended Harvard College, and graduated there at eighteen. Then he lived two years in the White House, Washington, during the presidency of his father, studying law and moving in society, where he met Webster, Clay, Jackson, and Randolph. Returning to Boston he devoted ten years to business and study, and wrote for the *North American Review*. He also undertook the management of his father's pecuniary affairs, and actively supported him in his contest in the House of Representatives for the right of petition and the anti-slavery cause. In 1848 he was prominent in politics as a "Conscience Whig," presiding over the Buffalo Convention which formed the Free Soil party and nominated Van Buren for president and himself for vice-president. As a member of the House of Representatives in that Congress which sat from 3rd December 1860 to 4th March 1861, he represented Massachusetts in the committee of

thirty-three at the time of the secession of seven of the Southern States. His selection by the chairman of this committee to present to the full committee certain propositions agreed upon by two-thirds of the republican members, and his calm and able speech of 31st January 1861 in the House, served to make him conspicuous before Congress and the country. Together with Seward, he stood for the republican policy of concession; and, while he was criticized severely, and charged with inconsistency in view of his record as a Conscience Whig, he was of the same mind as Lincoln, willing to concede non-essentials, but holding rigidly to the principle, properly understood, that there must be no extension of slavery. He believed that as the republicans were the victors they ought to show a spirit of conciliation, and that the policy of righteousness was likewise one of expediency, since it would have for its result the holding of the border slave States with the North until 4th March, when the republicans could take possession of the Government of Washington. With the incoming of the new administration Secretary Seward secured for Adams the appointment of minister to Great Britain. So much sympathy was shown in England for the southern cause that his path was beset with difficulties; but his mission was to prevent the interference of Great Britain in the struggle; and while the work of Lincoln, Seward, and Sumner, and the cause of emancipation, tended to this end, the American minister was insistent and unyielding, and knew how to present his case forcibly and with dignity. He laboured with energy and discretion to prevent the escape of the *Alabama*; and, when unsuccessful in this, he persistently urged upon the British Government its responsibility for the destruction of American merchant vessels by that cruiser. His reserve and frugidity, enforced by his diplomatic ability and high character, procured him the respect of the English, and were of marked assistance to him in his ministerial and social duties. In many emergencies he displayed coolness and courage of a high order. In his own diary he shows that underneath the calm exterior were serious trouble and keen anxiety; and, in fact, the strain which he underwent during the Civil war made itself felt in later years. Adams was instrumental in getting Earl Russell to stop the *Alexandra*, and it was his industry and pertinacity in argument and remonstrance that induced Russell to order the detention in September 1863 of the two iron-clad rams intended for the Southern Confederacy. Adams remained in England until May 1868. His last important work was as a member of the Tribunal of Arbitration at Geneva, which disposed of the "*Alabama* claims." His knowledge of the subject, and his fairness of mind, enabled him to render his country and the cause of international arbitration valuable service. He died at Boston on the 21st of November 1886.

An excellent biography of him has been written by his son, CHARLES F. ADAMS, in the *American Statesmen* series (1900). For his labours in editing works and memoirs, his private speeches and honorary degrees, see *Memoir in Massachusetts Historical Society Proceedings*, October 1899. (J. F. R.)

Adams, John Couch (1819-1892), British astronomer, was born at Lidcot farmhouse, Laneast, Cornwall, on 5th June 1819. His father, Thomas Adams, was a tenant farmer; his mother, Tabitha Knill Grylls, inherited a small estate at Badharlick. From the village school at Laneast he went, at the age of twelve, to Devonport, where his mother's cousin, the Rev. John Couch Grylls, kept a private school. His promise as a mathematician induced his parents to send him to the University of Cambridge, and in October 1839 he entered as a sizar at St John's College. He graduated B.A. in 1843 as the

senior wrangler and first Smith's prizeman of his year. While still an undergraduate he happened to read of certain unexplained irregularities in the motion of the planet Uranus, and determined to investigate them as soon as possible, with a view to ascertaining whether they might not be due to the action of an undiscovered planet beyond it. Elected fellow of his college in 1843, he at once proceeded to attack the novel problem. It was this: from the observed perturbations of a known planet to deduce by calculation, assuming only Newton's law of gravitation, the mass and orbit of an unknown disturbing body. By September 1845 he obtained his first solution, and handed to Professor Challis, the director of the Cambridge Observatory, a paper giving the elements of what he described as "the new planet." On 21st October 1845 he left at Greenwich Observatory, for the information of Airy, the astronomer royal, a similar document, still preserved among the archives. A fortnight afterwards Airy wrote asking a question about a point in the solution. Adams, who thought the point trivial, did not reply, and Airy for some months took no steps to verify by telescopic search the results of the young mathematician's investigation. Meanwhile, Le Verrier, on 10th November 1845, presented to the French Academy a memoir on Uranus, showing that the existing theory failed to account for its motion. Unaware of Adams's work, he attempted a like inquiry, and on 1st June 1846, in a second memoir, gave the position, but not the mass or orbit, of the disturbing body whose existence was presumed. The longitude he assigned differed by only 1° from that predicted by Adams in the document which Airy possessed. The latter was struck by the coincidence, and mentioned it to the Board of Visitors of the Observatory, Challis and Herschel being present. Herschel, at the ensuing meeting of the British Association early in September, accordingly ventured to predict that a new planet would shortly be discovered. Meanwhile Airy had in July suggested to Challis that the planet should be sought for with the Cambridge equatorial. The search was begun by a laborious method at the end of the month. On 4th and 12th August, as afterwards appeared, the planet was actually observed; but owing to the want of a proper star-map it was not then recognized as planetary. Le Verrier, still ignorant of these occurrences, presented on 31st August 1846 a third memoir, giving for the first time the mass and orbit of the new body. He communicated his results by letter to Dr Galle, of the Berlin Observatory, who at once examined the suggested region of the heavens. On 23rd September he detected near the predicted place a small star unrecorded in the map, and next evening found that it had a proper motion. No doubt remained that "Le Verrier's planet" had been discovered. On the announcement of the fact Herschel and Challis made known that Adams had already calculated the planet's elements and position. Airy at length published an account of the circumstances, and Adams's memoir was printed as an appendix to the *Nautical Almanac*. A keen controversy arose in France and England as to the merits of the two astronomers. In the latter country much surprise was expressed at the apathy of Airy; in France the claims made for an unknown Englishman were resented as detracting from the credit due to Le Verrier's achievement. As the indisputable facts became known, the world recognized that the two astronomers had independently solved the problem of Uranus, and to each ascribed an equal glory. The new planet, at first called *Le Verrier* by Arago, received by general consent the neutral name of *Neptune*. Its mathematical prediction was not only an unsurpassed intellectual feat; it showed also that Newton's law of gravitation, which Airy had almost called in

question, prevailed even to the utmost bounds of the solar system.

The honour of knighthood was offered to Adams when Queen Victoria visited Cambridge next year; but then, as on a subsequent occasion, his modesty led him to decline it. The Royal Society awarded him its Copley medal in 1848. In the same year the members of St John's College commemorated his success by founding in the University an Adams prize, to be given biennially for the best treatise on a mathematical subject. In 1851 he became president of the Royal Astronomical Society. His lay fellowship at St John's College came to an end in 1852, and the existing statutes did not permit of his re-election. Pembroke College, which possessed greater freedom, elected him in the following year to a lay fellowship, and this he held for the rest of his life. In 1858 he became professor of mathematics at St Andrews, but lectured only for a session, when he vacated the chair for the Lowndean professorship of astronomy and geometry at Cambridge. Two years later he succeeded Challis as director of the Observatory, where he resided until his death. In 1863 he married Miss Eliza Bruce, of Dublin, who survived him.

Although Adams's researches on Neptune were those which attracted widest notice, the work he subsequently performed in relation to gravitational astronomy and terrestrial magnetism was not less remarkable. Several of his most striking contributions to knowledge originated in the discovery of errors or fallacies in the work of his great predecessors in astronomy. Thus in 1852 he published new and accurate tables of the moon's parallax, which superseded Burckhardt's, and supplied corrections to the theories of Damoiseau, Plana, and Pontécoulant. In the following year his memoir on the secular acceleration of the moon's mean motion disproved the validity of Laplace's famous explanation, which had held its place unchallenged for sixty years. At first, Le Verrier, Plana, and others abroad disputed the soundness of Adams's startling result; but further inquiry established beyond question that he was right, and his memoir produced nothing less than a revolution in this branch of theoretical astronomy. The Royal Astronomical Society in 1866 awarded him its gold medal for these researches. The great meteor shower of 1866 turned his attention to the Leonids, whose probable path and period had already been discussed by Professor H. A. Newton. Using a powerful and elaborate analysis, Adams ascertained that this cluster of meteors, which belongs to the solar system, traverses a nearly circular orbit in $33\frac{1}{2}$ years, and is subject to definite perturbations from the larger planets, Jupiter, Saturn, and Uranus. These results were published in 1867. Ten years later, when Mr G. W. Hill of Washington brought out a new and beautiful method for dealing with the problem of the lunar motions, Adams announced in a brief notice his own work in the same field, which had followed a parallel course. His results confirmed and supplemented Hill's. In 1874-76 he was president of the Royal Astronomical Society for the second time, when it fell to him to present the gold medal of the year to Le Verrier. The determination of the constants in Gauss's theory of terrestrial magnetism occupied him at intervals for over forty years. The calculations involved great labour, and were not published during his lifetime. They were edited by his brother, Professor W. Grylls Adams, and appear in the second volume of the collected *Scientific Papers*. Numerical computation of this kind might almost be described as his pastime. The value of the constant known as Euler's, and the Bernoullian numbers up to the 62nd, he worked out to an unimagined degree of accuracy. For Newton and his writings he had a boundless admira-

tion; many of his papers, indeed, bear the cast of Newton's thought. He laboured for many years at the task of arranging and cataloguing the great collection of Newton's unpublished mathematical writings, presented in 1872 to the University by Lord Portsmouth. The account of these, issued in a volume by the University Press in 1888, is by his hand. The post of Astronomer Royal was offered him in 1881, but he preferred to pursue his peaceful course of teaching and research in Cambridge. He was British delegate to the International Prime Meridian Conference at Washington in 1884, when he also attended the meetings of the British Association at Montreal and of the American Association at Philadelphia. Five years later his health gave way, and after a long illness he died at the Cambridge Observatory on 21st January 1892, and was buried in St Giles' cemetery, near his home. An international committee was formed for the purpose of erecting a monument to his memory in Westminster Abbey; and there, in May 1895, a portrait medallion, by Albert Bruce Joy, was placed near the grave of Newton, and adjoining the memorials of Darwin and of Joule. His bust, by the same sculptor, stands opposite that of Herschel in the hall of St John's College, Cambridge, of which both were fellows. Herkomer's portrait is in Pembroke College; and Mogford's, painted in 1851, is in the combination room of St John's. Another bust, taken in his youth, belongs to the Royal Astronomical Society. A memorial tablet, with an inscription by Archbishop Benson, is placed in the cathedral at Truro; and Mr Passmore Edwards erected a public institute in his honour at Launceston, near his birthplace.

The Scientific Papers of John Couch Adams, 4to, vol. i. (1896), and vol. ii. (1900), edited by William Grylls Adams and Ralph Allen Sampson, with a memoir by Dr J. W. L. Glaisher, and his *Lectures on the Lunar Theory*, edited by Professor Sampson, have been published by the Cambridge University Press. (D. M. *)

Adana, (1) a Turkish vilâyet in the S.E. of Asia Minor, which includes the ancient Cilicia. The mountain districts are rich in mineral wealth, and the fertile coast-plain is well watered by the rivers that descend from the Taurus range. Imports and exports pass through Mersina. Pop. 405,000 (Moslems, 158,000; Ansariéh, &c., 73,000; Christians, 174,000). (2) The chief town of the vilâyet, situated in the alluvial plain on the right bank of the Sihûn, *Sarus*, which is navigable for small craft to its mouth. It is connected with Tarsus and Mersina by a railway built in 1887, and has good buildings, river-side quays, cotton-mills, and an American mission with church and schools. Adana, which retains its ancient name, rose to importance as a station on the Roman military road to the east, and was at one time a rival of Tarsus. During the Middle Ages it often changed hands and suffered many vicissitudes. It is the seat of a British vice-consul. Population, 31,000 (Moslems, 14,000; Christians and Ansariéh, 17,000).

Adelaide, the capital of South Australia, 7 miles from the mouth of the Torrens river, in 34° 57' S. lat. and 138° 38' E. long. Built on a broad plain running between a range of mountains and the gulf of St Vincent, it is connected by rail with the sea at several points besides Port Adelaide—7½ miles away, including Largs Bay, where the great ocean liners anchor. It is also the terminus of an extensive railway system, of which the main line runs through Melbourne, Sydney, and Brisbane to Rockhampton. Of late years the population, and more especially that of the outlying suburbs, has rapidly increased. The city generally contained in 1901 38,981 inhabitants; the city and suburbs within a 10-mile radius, 162,094.

The principal suburbs are Burnside, 7763; Glenelg (like Semaphore, a resort on the coast of the gulf), 3946; Hindmarsh, 9984; Kensington and Norwood, 12,562; Port Adelaide, 20,062; St Peter's, 7605; Thebarton, 5297; and Unley, 18,119. The streets are generally broad, well kept, and well drained; horse tramcars run through the principal thoroughfares; and arrangements have been made with a private company to light certain parts of the city with electricity. A university was established in 1874, and receives a Government grant of £3200 per annum. It has also been magnificently endowed by Sir Thomas Elder, a former citizen, who presented £30,000 for a medical school, £20,000 for arts and science faculties, £20,000 for a chair of music, and £25,000 for the general funds of the university. Other educational institutions include a technical college with over 300 scholars, and a school of mines and industries with over 800. There are extensive Government buildings and law courts, a fine museum and free library, an institute containing a library, an art gallery containing several splendid specimens of modern art, a town hall, a stock exchange, two handsome markets—one the property of the corporation, a hospital, two theatres, an academy of music, city baths, two lunatic asylums, and several charitable institutions. The general post office also deserves special mention, being one of the finest in Australasia. The large hall of the exhibition building is largely used for the purpose of entertainments. Among the monuments are one to Colonel Light, the founder of the colony, statues of Queen Victoria and Robert Burns, and copies of the Farnese Hercules and Canova's Venus. The city is surrounded by park lands, and also contains botanic gardens and a fine collection of zoological specimens. Near Glenelg stands Morpethville racecourse. The thermometer in summer frequently stands as high as 110° F. in the shade, hot winds blowing the while from the interior, but during the rest of the year the climate is mild and pleasant. During a period of about thirty years the mean annual rainfall has been 20·4 inches.

The Adelaide city government is regarded as more progressive than that of any other Australian capital. The municipal council consists of a mayor and six aldermen, elected by the whole body of ratepayers, and twelve councillors elected by six wards. In no other Australian city is the mayor elected by the ratepayers generally. The drainage is managed on a carefully-planned system. For the water-supply there are three storage reservoirs, with a capacity of about 3,550,000,000 gallons of water, and several service reservoirs. The telephone system is owned by the state. South Adelaide is the principal business part of the city, which is the central share-market in Australia for the West Australian gold-fields, and also for the silver-mines of Broken Hill, and the copper-mines of Wallaroo, Burra Burra, and Moonta in South Australia. Viewed from the standpoint of trade Port Adelaide is the third port of Australia. In 1900 the imports were valued at £4,739,483, and the exports at £4,363,971. This suburb is also an important manufacturing centre. Altogether four daily newspapers are issued in Adelaide. (J. D. F.)

Adelsberg (Slovene, *Postojna*), a market town in the Austrian duchy of Carniola, chief town of the district of the same name. Population of commune (1890), 3597, of whom 140 were German and the remainder Slovenes; (1900), 3636. The total length of the passages in the celebrated stalactite cavern, about a mile from the town, is now over 5½ miles. The connexion with the Ottokar Grotto was established in 1890. The Magdalene Grotto, about an hour's walk to the north, is celebrated for the extraordinary subterranean amphibian, the *proteus anguinus*, first discovered there. It is about a foot in length, lives on snails and worms, and is provided with both lungs and gills.

Aden, a seaport and territory in Arabia, politically part of British India, under the governor of Bombay. The seaport is situated in 12° 45' N. lat. and 45° 4' E. long.

on a peninsula near the entrance to the Red Sea. It was first occupied by the British in January 1839. From time to time additional land on the mainland has been acquired by cession or purchase, and the adjoining island of Perim, lying in the actual mouth of the strait, was permanently occupied in 1857. Further inland, and along the coast, most of the Arab chiefs are under the political control of the British Government, which pays them regular allowances. The area of the peninsula is only 15 square miles, but the total area of British territory is returned at 80 square miles, including Perim (5 square miles). In 1891 the population was 44,079, of whom no less than 30,914 were males. In 1901 the population was 41,222, showing a decrease of 6 per cent. The average density is 515 persons per square mile. The gross revenue in 1897-98 was Rs.38,07,539, and the municipal income Rs.1,93,922. There are 42 schools, with 1949 pupils, being 5.6 per cent. of the population. There are three printing presses, of which one is in the jail, and the other two belong to a European and a Parsi firm of merchants. In 1900 Aden suffered from an epidemic outbreak of plague.

Aden is strongly fortified, with a permanent garrison of one British and one native regiment, two batteries of artillery, and one company of engineers. The administration is conducted by a political resident, who is also the military commandant. All food requires to be imported, and the water-supply is largely derived from condensation. A little water is obtained from wells, and some from an aqueduct 7 miles long, constructed in 1867 at a cost of £30,000, besides an irregular supply from the old reservoirs. The importance of Aden as a port of call for steamers and a coaling station has grown immensely since the opening of the Suez Canal. It also conducts a considerable trade with the interior of Arabia, and with the Somali coast of Africa on the opposite side of the Red Sea. The submarine cables of the Eastern Telegraph Company here diverge—on the one hand to India, the Far East, and Australia, and on the other hand to Zanzibar and the Cape. The number of steamers visiting the port rose from 535 in 1871-72 to 1214 in 1881-82. In 1897-98 the total number of merchant vessels that entered and cleared was 2496, of which 1080 with a tonnage of 2,124,043 were steamers. The number that called to discharge or take cargo was 816. In addition, 129 British and foreign men-of-war and troopships called at the port. In 1897-98, the total volume of trade amounted, in tens of rupees, to 8,188,393, which is classified into foreign, India, and inland. Of the foreign, the imports amounted to Rx. 2,851,193, and the exports to Rx. 3,345,028. Of the Indian, the imports were Rx. 1,250,054, and the exports Rx. 258,800. Of the inland, the imports were Rx. 337,640 and the exports Rx. 145,678. The principal articles of import are coffee, cotton-piece goods, &c., grain, hides, coal, opium, cotton-twist and yarn. The exports are, in the main, a repetition of the imports. Of the total imports, nearly one-third come from the east coast of Africa, and another third from Arabia.

Of the total exports, nearly one-third again go to the east coast of Africa. In 1897-98 the share of the United Kingdom was only 13 per cent. of the total imports, and 6 per cent. of the total exports. In that year the receipts of the port trust amounted to Rs.2,48,975, and the expenditure to Rs.2,70,511. The number of vessels that called at Perim was 556, of which 396 were British.

(J. S. Co.)

Adernò, a town of Italy, Sicily, prov. Catania, situated at the S.W. foot of Mount Etna, 22 miles N.W. from Catania by the circum-Etna railway. It has a square Norman tower (now converted into a prison) and a monastery (1157), both built by the Norman count Roger of Sicily; some slight remains survive of the ancient Sikelian city of *Hadranum*, and of its famous temple to Hadranus. Adernò is famous for its oranges, and has flour-mills. Population (1871), 14,613; (1881), 19,180; (1901), 25,873.

Adiquala. See ERITREA.

Adirondacks, a group of mountains in north-eastern New York, U.S.A., a portion of the Appalachian system of eastern North America, occupying the eastern part of the region between Lake Champlain and Lake Ontario, north of the Mohawk Valley. They do not form a connected range, but consist of many summits, isolated or in groups, arranged with little appearance of system. The highest peak, Mount Marcy, altitude 5344 feet, is near the eastern part of the group, and about it are many summits exceeding 4000 in height. These mountains, consisting mainly of somewhat homogeneous granite rocks, are the result of long-continued erosion, carried on in a greatly elevated region, by which the softer areas have suffered the most and the harder the least. In recent geologic times this area, with the exception of the higher summits, was covered by the Laurentian glacier, whose erosion, while perhaps having little effect on the larger features of the country, has greatly modified it in details, producing many lakes and ponds, together with rapids and falls in the streams. The region is heavily forested with spruce, pine, and broad-leaved trees, forming the only continuous forest area remaining in the state. In order to preserve these forests from destruction the state withholds its lands from sale, and as opportunity offers, increases its holdings by purchase. In 1900 the area of state lands comprised 1,250,000 acres. The Adirondack region, with its mountains, lakes, and forests, presents much beautiful, and even grand, scenery, and is greatly frequented in summer as a resort and sanatorium.

ADMIRALTY ADMINISTRATION.

BRITISH EMPIRE.

I. **THE Administrative System.**—That the navy is the only real defence of the British islands has been recognized by English people ever since the days of King Offa, who died in 796, leaving to his successors the admirable lesson that "he who would be secure on land must be supreme at sea." The truth of the lesson thus learnt is sanctioned by all the experience of English history, and Parliament has repeatedly enforced the fact. The navy is the only force that can safeguard the British islands from hostile descents; it is the only force that can protect their vast sea-borne commerce and food supplies; by giving safety to the home country it sets British troops free for operations abroad, and makes their passage secure; and thus, as also by giving command of the sea, the fleet is the means by which the empire is guarded and has become a true imperial bond.

British naval administration is conducted by the Board

of Admiralty, and the function of that board is the maintenance and expansion of the fleet in accordance with the policy of the Government, and the supplying of it with trained officers and men; its distribution throughout the world; and its preservation in readiness and efficiency in all material and personal respects. The character of the Admiralty Board is peculiar to the British constitution, and it possesses certain features which distinguish it from other departments of the State. The business it conducts is very great and complex, and the machinery by which its work is done has grown with the expansion of that business. The whole system of naval administration has been developed historically, and is not the product of the organized skill of one or a few individuals, but an organic growth possessing marked and special characteristics. The Admiralty Board derives its character from the fact that it represents the Lord High Admiral, and that its powers and operation depend much more upon usage than upon

The Board of Admiralty.

those instruments which actually give it authority, and which, it may be remarked, are not in harmony among themselves. The executive operations are conducted by a series of civil departments which have undergone many changes before reaching their present constitution and relation to the Board. The salient characteristic of the Admiralty is a certain flexibility and elasticity with which it works. Its members are not, in a rigid sense, heads of departments. Subject to the necessary and constitutional supremacy of the Cabinet Minister at their head, they are jointly and co-equally "commissioners for executing the office of High Admiral of the United Kingdom, and of the territories thereunto belonging, and of High Admiral of the colonies and other dominions." The members of the Board are in direct and constant communication with the First Lord and with one another, as also with the civil departments which work under their control. It was enjoined by James I. that the principal officers and commissioners of the navy should be in constant communication among themselves, consulting and advising "by common council and argument of most voices," and should live as near together as could conveniently be, and should meet at the navy office at least twice a week. This system of intercommunication still exists in a manner which no system of minutes could give; and it may be remarked, as illustrative of the flexibility of the system, that a Board may be formed on any emergency by two Lords and a secretary, and a decision arrived at then and there. Such an emergency Board was actually constituted some years ago on board the Admiralty yacht in order to deal on the instant with an event which had just occurred in the fleet. At the same time it must be remarked that, in practice, the First Lord being personally responsible under the Orders in Council, the operations of the Board are dependent upon his direction.

The present system of administering the navy dates from the time of Henry VIII. The naval business of the country had so greatly expanded in his reign that we find the Admiralty and Navy Board reorganized or established; and it is worthy of remark that there existed at the time an Ordnance branch, the navy not yet being dependent in that matter upon the War Department.¹ The Navy Board administered the civil departments under the Admiralty, the directive and executive duties of the Lord High Admiral remaining with the Admiralty office. A little later the civil administration was vested in a Board of principal officers subordinate to the Lord High Admiral, and we can henceforth trace the work of civil administration being conducted under the navy and victualling boards apart from, but yet subject to, the Admiralty itself. This was a system which continued during the time of all the great wars, and was not abolished until 1832, when Sir James Graham, by his reforms, put an end to what appeared a divided control. Whatever may have been the demerits of that system, it sufficed to maintain the navy in the time of its greatest achievements, and through all the wars which were waged with the Spaniards, the Dutch, and the French. The original authority for the present constitution of the Admiralty Board is found in a declaratory Act of the 2 William and Mary, c. 2, in which it is enacted that "all and singular authorities, jurisdictions, and powers which, by Act of Parliament or otherwise, had been lawfully vested" in the Lord High Admiral of England had always

appertained, and did and should appertain to the commissioners for executing the office for the time being "to all intents and purposes as if the said commissioners were Lord High Admiral of England." The Admiralty commission was dissolved in 1701, and reconstituted on the death of Prince George of Denmark, Lord High Admiral in 1709. From that time forward, save for a short period in 1827-28, when the Duke of Clarence was Lord High Admiral, the office has remained in commission.

It is unnecessary to describe in detail the many changes which have passed over the system of naval administration up to the present time. When Lord St Vincent accepted office under the Addington ministry in 1801, it fell to him to deal with a vast system of waste, extravagance, and malversation of public funds. The work of reform was too vast even for this strong administrator to accomplish, and the great seaman became the object of a torrent of virulent abuse embodied in an extraordinary pamphlet literature. When the Addington ministry fell he left office, but the work he had done bore good fruit later. The investigations which were conducted at that time were essentially the basis of the reorganization effected by Sir James Graham under the administration of Earl Grey. That reorganization involved the abolition of the Board of principal officers and commissioners of the navy, and the commissioners for victualling, the whole business of naval administration being concentrated under the immediate direction of the Board of Admiralty. The "Act to amend the laws relating to the business of the civil departments of the navy, and to make other regulations for more effectually carrying on the duties of the said departments" (2 William IV. c. 40), vested in the Admiralty Board all the powers of the commissioners of the civil departments, and provided for the creation of five separate and independent responsible superintendents of departments under the Admiralty collectively, and the several Lords individually. These new officers were the surveyor of the navy, the accountant-general, the storekeeper-general, the controller of victualling and transports, and the physician of the navy, whose title in 1843 became director-general of the medical department of the navy. A number of changes have since been made, but the general principle remains the same, and the constitution of the Admiralty Board and civil departments is described below. The Board consisted of the First Lord and four Naval Lords with a Civil Lord, who were accustomed to meet sometimes daily, but at all times frequently; and the system developed provided for the sub-division of labour, and yet for the co-ordinated exertion of effort.

A fresh system, at variance with Admiralty tradition and practice, was introduced by Mr Childers in 1869. But those changes have now almost entirely been reversed. The system of intercommunication in the Board was paralysed by an attempt to lay down definite rules of practice and to define what was essentially indefinable. When Mr Goschen succeeded Mr Childers he found it necessary to modify the system; and since that time it may be said that the Admiralty Board has resumed, broadly, the character which it had after the reorganization of Sir James Graham. The merits of that system, as conducing to elasticity and flexibility of working, have been pointed out; and, whatever its disadvantages, it is not to be denied that the system has worked well in practice, and has certainly won the approval and the admiration of many statesmen.² Lord George Hamilton said, before the Royal Commission on civil establishments, 1887, that "It has this advantage,

¹ The Board of Ordnance was originally instituted for the navy, but eventually fell into military hands, to the detriment of the navy—the only navy of any nation that has not full authority over its own ordnance. In 1653, according to Oppenheim, it was, owing to its inefficiency, placed under the Admiralty. In 1632 it appears to have been independent but "still retained that evil pre-eminence in sloth and incapacity it had already earned and has never since lost."

² The Duke of Somerset, Lord Halifax, Sir J. Graham, Sir F. Baring, and others stated that "the administrative system contrasted most favourably with any department they had been connected with," as did the more recent commission under Lord Hartington's presidency.

that you have all departments represented round a table, and that if it is necessary to take quick action, you can do in a few minutes that which it would take hours under another system to do"; and the report of the Royal Commission of 1889 remarked that "The constitution of the Board of Admiralty appears to us well designed, and to be placed under present regulations on a satisfactory footing."

The special characteristics of the Admiralty Board which have been described are accompanied by a very peculiar and noteworthy feature, which is not without relation to the untrammelled and undefined operations of the Admiralty. This feature arises from the discrepancy between the Admiralty patent and the Orders in Council, for the Admiralty is not administered according to the terms of the patent which invests it with authority, and its operations raise a singular point in constitutional law.

The legal origin of the powers exercised by the First Lord and the Board itself is indeed curiously obscure. Under the patent the full power and authority are conferred upon "any two or more" of the commissioners, though, in the patent of Queen Anne, the grant was to "any three or more of you." It was under the Act 2 Will. IV. c. 40 that two Lords received the necessary authority to legalize any action of the Board; but already, under an Act of 3 George IV., two Lords had been empowered to sign so long as the Board consisted of six members. We therefore find that the legal authority of the Board under the patent is vested in the Board; but in the Order in Council of 14th January 1869 the sole responsibility of the First Lord was officially laid down, and in the Order in Council of 19th March 1872 the First Lord was made "responsible to your Majesty and to Parliament for all the business of the Admiralty." As a matter of fact, the authority of the First Lord, independent of his colleagues, had existed in an undefined manner from ancient times. Before a select committee of the House of Commons in 1861 the Duke of Somerset stated that he considered the First Lord responsible, that he had always "acted under that impression," and that he believed "all former First Lords were of this opinion"; while Sir James Graham said that "the Board of Admiralty could never work, whatever the patent might be, unless the First Lord were supreme, and did exercise constantly supreme and controlling authority." It is not, therefore, surprising to find that there has been undoubtedly direct government without a Board. Thus, in the operations conducted against the French channel ports in 1803-4, Lord Melville, then First Lord, took steps of great importance without the knowledge of his colleagues, though he afterwards bowed to their views, which did not coincide with his own. Again, when Lord Gambier was sent to Copenhagen in 1807, he was instructed to obey all orders from the King, through the principal Secretary of State for war, and in this way received orders to attack Copenhagen, which were unknown to all but the First Lord. In a similar way the secretary of the Admiralty was despatched to Paris in 1815 with instructions to issue orders as if from the Board of Admiralty when directed to do so by the foreign secretary who accompanied him, and these orders resulted in Napoleon's capture. These instances were cited, except the first of them, by Sir James Graham before the select committee of the House of Commons in 1861, in order to illustrate the elastic powers under the patent which enabled the First Lord to take immediate action in matters that concerned the public safety. It is not surprising that this peculiar feature of Admiralty administration should have attracted adverse criticism, and have led some minds to regard the Board as "a fiction not worth keeping up"—a view expressed

by Mr Baxter, parliamentary secretary in 1871. There have been instances of the power of the First Lord being misused, and in relation to the loss of the *Captain* in 1870, it seemed a legitimate conclusion to draw from the evidence before the House of Lords committee that Mr Childers, being himself nominally responsible for sending this vessel to sea, constituted himself a judge of the case, and, exempting himself from blame, distributed censure among a number of persons, while he placed the chief weight on the Controller, who had been by a former board specially released from this responsibility.¹ The truth is that there existed antecedently to the Admiralty patents, and now concurrently exists with them, an undefined power based upon usage enabling the First Lord to act independently of his colleagues. This is a feature of administration that evidently springs from necessity and political expediency.

The case of the *Captain* had a beneficial effect upon Admiralty administration. It caused the Board to be reinstated in its former position, and gave once more to the system those advantages of intercommunication and consultation which have been alluded to. It cannot be said, however, that the question of ultimate responsibility is well defined. The Duke of Somerset, Sir James Graham, and Sir Charles Wood, afterwards Lord Halifax, held the view that the First Lord was singly and personally responsible for the sufficiency of the fleet. Sir Arthur Hood expressed before the House of Commons committee in 1888 the view that the Board collectively were responsible; whilst Sir Anthony Hoskins assigned the responsibility to the First Lord alone with certain qualifications, which is a just and reasonable view.

II. *Admiralty Organization.*—Under the organization which now exists, the Board of Admiralty consists of the First Lord, the first and second Naval Lords, the Additional Naval Lord and Controller, the junior Naval Lord, and the Civil Lord, who are commissioners for executing the office of Lord High Admiral, and with them are the parliamentary and financial secretary and the permanent secretary. As has been explained, the First Lord is responsible under the Orders in Council to the Crown and to Parliament for all Admiralty business. In the hands of the other Lords and secretaries rest duties very carefully defined, and they direct the civil departments which are the machinery of naval administration. The first Naval Lord, the second Naval Lord, and the junior Naval Lord are responsible to the First Lord in relation to so much of the business concerning the personnel of the navy and the movements and condition of the fleet as is confided to them, and the Additional Naval Lord or Controller is responsible in the same way for the material of the navy; while the parliamentary secretary has charge of finance and some other business, and the Civil Lord of all shore works—i.e., docks, buildings, &c.—and the permanent secretary of special duties. The First Lord of the Admiralty is the cabinet minister through whom the navy receives its political direction in accordance with imperial policy. He is the representative of the navy in Parliament, which looks to him for everything concerned with naval affairs. The members of the Board are his advisers; but if their advice is not accepted, they have no remedy except protest or resignation. It cannot be denied that the responsibility of the members of the Board, if their advice should be disregarded, must cease, and it is sufficiently obvious that the remedy of resignation will not always commend itself to those whose position and advancement depend upon the favour of the Government.

¹ The late Admiral Sir Cooper Key, when director of naval ordnance during Mr Childers's administration, observed to the writer that no First Lord of the Admiralty knew so little of the working of the Admiralty as Mr Childers, because, owing to the discontinuance of Board meetings, he lost the great advantage of hearing the discussion. (R. V. H.)

Something will be said a little later concerning the working of the system and the relation of the First Lord to the Board in regard to the navy estimates. In addition to general direction and supervision, the First Lord has special charge of promotions and removals from the service, and of matters relating to honours and rewards, as well as the appointments of flag officers, captains, and other officers of the higher ranks. With him rests also the nomination to naval cadetships for the major part and assistant clerkships.

Apart from the First Lord, the first Naval Lord is the most important officer of the Board of Admiralty. It seems to be unquestionable that Sir James Graham was right in describing the senior Naval Lord as his "first naval adviser." Theoretically, the first Naval Lord is responsible for the personnel of the fleet; but in practice he is necessarily concerned with the material also as soon as it is put into commission, and with the actual commissioning of it. It is correct to say that he is chiefly concerned with the employment of the fleet, though his advice has weight in regard to its character and sufficiency, and is always sought in relation to the shipbuilding programme. Broadly speaking, the first Naval Lord's duties and authority cover the fighting efficiency and employment of the fleet, and upon him and upon the Controller the naval business of the country largely falls. He directs the operations of the admiral superintendent of naval reserves in regard to ships, the hydrographer, the director of naval ordnance, so far as the gunnery and torpedo training establishments are concerned, and the naval intelligence department, and he has charge of all matters relating to discipline. The mobilization of the fleet, both in regard to personnel and material, also falls to him, and among a mass of other business in his department are necessary preparations for the protection of trade and the fisheries. It will thus be seen that the first Naval Lord is the chief officer of the Board of Admiralty, and that the operations of the other members of the Board all have relation to his work, which is no other than preparation for war. It may here be remarked that it appears most necessary to change the Naval Lords frequently, so that there may always be in the Board some one who possesses recent touch with the service afloat.

The second Naval Lord may be regarded as the coadjutor of the first Naval Lord, with whose operations his duties are very closely related, though, like every other member of the Board, he is subordinate only to the First Lord. The duties of the second Naval Lord are wholly concerned with the personnel of the fleet, the manning of the navy, and mobilization. In his hands rests the direction of naval education, training, and the affairs of the royal marine forces. The training establishments and colleges are in his hands. He appoints navigating officers and lieutenants to ships (unless they be to command), sub-lieutenants, midshipmen, and cadets, engineer officers, gunners, and boatswains, and supervises the management of the reserve. In his province is the mobilization of the personnel, including the coastguard and the royal naval reserve. Necessarily, the first and second Naval Lords work together, and upon occasion can replace each other. It was explained to the House of Lords committee in 1871—and the condition still prevails—that the two senior Naval Lords—at that time Admiral Sir Frederick Grey and Vice-Admiral Eden—were in constant communication in relation to the complements of ships and the manning of the fleet, and that each knew intimately the other's work, and when necessary could take charge of it with perfect confidence.¹

Most important are the duties that fall to the Additional Naval Lord and Controller. He has charge of everything

that concerns the material of the fleet, and his operations are the complement of the work of the first Naval Lord. A great number of civil departments are directed by the Controller, and his survey and supervision extend to the dockyards and building establishments of the fleet. He submits plans to the board for new ships, and is responsible for carrying into effect its decisions in regard to all matters of construction and equipment. The building operations both in the dockyards and in private yards are therefore under his supervision. In regard to all these matters, the director of naval construction and the engineer-in-chief are the heads of the civil departments that carry on the work. Again, the Controller is responsible in regard to armament—both gunnery and torpedo—and it is the work of his department to see to all gunnery and torpedo fittings, and to magazines, shell-rooms, and electric apparatus. The officer in immediate charge of this branch of the Controller's work, under his direction, is the director of naval ordnance. In regard to work at the dockyards (*q.v.*) the Controller is aided by the director of dockyards. He supervises this officer in preparing the programme of work done in the dockyards, the provision of the material required, and its appropriation to particular work in accordance with the programme. Other officers who conduct great operations under the authority and responsibility of the Controller, are the director of stores, who maintains all necessary supplies of coal and stores at home and abroad, and examines the store accounts of ships, and the inspector of dockyard expense accounts, who has charge of the accounts of dockyard expenditure and seeing that outlay is charged as directed. In regard to the navy estimates, the Controller, through his subordinates, is responsible for the preparation and administration of votes 8 and 9 (those for shipbuilding and naval armaments), except in regard to some sub-headings of the former, and thus in the year 1900-1 for the expenditure of something like £15,000,000.

The junior Naval Lord has in his hands the very important duties that are concerned with the transport, medical, and victualling services, as well as the regulation of hospitals, the charge of coaling arrangements for the fleet, and other duties that conduce to the practical efficiency of the navy. He also appoints chaplains, naval instructors, medical officers (except in special cases), and officers of the accountant branch. A vast business in regard to the internal economy of ships greatly occupies the junior Lord. He has charge, for example, of uniforms, prize-money, bounties, naval savings banks, and pensions to seamen and marines, and the widows of naval and marine officers. The work of the junior Naval Lord places under his direction the director of transports, the director-general of the Medical Department, the director of victualling, and, in regard to particular matters, the director of stores, the accountant-general, the chaplain of the fleet, and the Intelligence Department, so far as the junior Lord's department is concerned.

The Civil Lord supervises, through the director of works, the Works Department, dealing with Admiralty buildings and works, construction and labour, contracts, and purchases of building stores and land. He is also responsible for the civil staff of the naval establishments, except in regard to certain officials, and for duties connected with Greenwich Hospital, compassionate allowances, charitable funds, and business of like character. The accountant-general, in regard to these matters, is directed by him, and the director of Greenwich Hospital is under his authority.

The parliamentary and financial secretary is responsible for the finance of the department, the navy estimates, and matters of expenditure generally, and is consulted in regard to all matters involving reference to the Treasury.

¹ The drawback is, that a Naval Lord can only go on leave by throwing all his work on a colleague already overweighed with work.

His position in regard to estimates and expenditure is very important, and the accountant-general is his officer, while he has financial control over the director of contracts. The financial secretary also examines proposals for new expenditure.

A most important official of the Board is the permanent secretary, whose office has been described as the "nerve-centre" of the Admiralty, since it is the channel through which papers for the Lords of the Admiralty pass for the inter-communication of departments and for the correspondence of the Board. The tradition of Admiralty procedure largely rests with the permanent secretary, and it is most important that he should be chosen from one of the branches, and should have served in as many of them as possible, in order that he may possess a thorough knowledge of the theory and practice of the Admiralty system. In addition to the secretarial duties of the permanent secretary's department, the permanent secretary has charge of the military, naval, and legal branches, each under a principal clerk, the civil branch, and the record office. The various branches deal with matters concerning the commissioning of ships and the distribution of the fleet, and the manning and discipline of the navy, with other associated matters, being the channels for the operations of the Naval Lords. It is a highly important function of the department of the permanent secretary to preserve the inter-related working of the various departments, and to keep unbroken the thread of administration when a new Board is constituted.

The following is a list of the First Lords and first Naval Lords since 1832:—

<i>First Lords.</i>	<i>Senior Naval Lords.</i>
Sir James R. G. Graham, Bart., November 1830.	Rear-Adm. Sir Thomas M. Hardy.
Lord Auckland, June 1834.	(1) Rear-Adm. Sir Thomas M. Hardy.
Earl de Grey, December 1834.	(2) Rear-Adm. the Hon. George H. L. Dundas.
Lord Auckland, April 1835.	(3) Rear-Adm. Sir Charles Adam.
The Earl of Minto, G.C.B., September 1835.	Vice-Adm. Sir John P. Beresford, K.C.B.
The Earl of Haddington, Sep- tember 1841.	Rear-Adm. Sir Charles Adam.
The Earl of Ellenborough, Janu- ary 1846.	Adm. Sir George Cockburn, G.C.B.
The Earl of Auckland, July 1846.	Adm. Sir George Cockburn, G.C.B.
Sir Francis Thornhill Baring, Bart., January 1849.	(1) Vice-Adm. Sir Charles Adam, K.C.B.
The Duke of Northumberland, K.G., February 1852.	(2) Rear-Adm. James W. D. Dundas, C.B.
Sir James R. G. Graham, Bart., January 1853.	(1) Rear-Adm. James W. D. Dundas, C.B.
Sir Charles Wood, March 1855.	(2) Rear-Adm. the Hon. M. Fitzhardinge Berkeley, C.B.
Sir John Pakington, Bart., March 1858.	(1) Rear-Adm. the Hon. M. Fitzhardinge Berkeley, C.B.
The Duke of Somerset, June 1859.	(2) Rear-Adm. the Hon. Sir Richard S. Dundas, K.C.B.
Sir John S. Pakington, Bart., G.C.B., July 1866.	Vice-Adm. William Fanshawe Martin.
Rt. Hon. Henry Thomas Lowry Corry, March 1867.	(1) Vice-Adm. the Hon. Sir Richard S. Dundas, K.C.B.
Rt. Hon. Hugh Culling Eardley Childers, December 1868.	(2) Rear-Adm. the Hon. Sir Frederick W. Grey, K.C.B.
	Vice-Adm. Sir Alexander Milne, K.C.B.
	Vice-Adm. Sir Alexander Milne, K.C.B.
	Vice-Adm. Sir Sydney C. Dacres, K.C.B.

First Lords.
Rt. Hon. George J. Goschen,
March 1871.

Rt. Hon. George Ward Hunt,
March 1874.

Rt. Hon. William Henry Smith,
August 1877.

The Earl of Northbrook, May
1880.

Lord George Hamilton, July
1885.

The Marquis of Ripon, K.G.,
February 1886.

Lord George Hamilton, August
1886.

Earl Spencer, K.G., August
1892.

Rt. Hon. George J. Goschen,
July 1895.

The Earl of Selborne, November
1900.

Senior Naval Lords.
(1) Vice-Adm. Sir Sydney C. Dacres, K.C.B.

(2) Adm. Sir Alexander Milne,
G.C.B.

(1) Adm. Sir Alexander Milne,
G.C.B.

(2) Adm. Sir Hastings R. Yel-
verton, G.C.B.

(1) Adm. George G. Wellesley,
C.B.

(2) Adm. Sir Astley Cooper
Key, K.C.B.

Adm. Sir Astley Cooper Key,
K.C.B.

Vice-Adm. Arthur W. Acland
Hood, C.B.

Adm. Lord John Hay, K.C.B.

(1) Adm. Sir Arthur W. Acland
Hood, K.C.B.

(2) Adm. Sir R. Vesey Hamil-
ton, K.C.B.

(3) Adm. Sir Anthony H. Hos-
kine, K.C.B.

(1) Adm. Sir Anthony H. Hos-
kine, K.C.B.

(2) Adm. Sir Frederick W.
Richards, K.C.B.

(1) Adm. Sir Frederick W.
Richards, K.C.B.

(2) Vice-Adm. Lord Walter
Kerr, K.C.B.

Adm. Lord Walter Kerr, K.C.B.

III. *Business and Responsibility.*—The manner in which the Admiralty Board conducts the great operations under its charge has been indicated. It would be impossible here to describe it in detail, though something concerning the civil departments, which are the machinery of naval administration, will be found below. It will, however, indicate the character of Admiralty administration if we explain to some extent the conditions which surround the preparation of the estimates and the shipbuilding programme, the more so because this matter has been the battle ground of critics and supporters of the Admiralty. It has already been pointed out that the Naval Lords, if they dissent from the estimates that are presented, have no remedy but that of protest or resignation. Into the controversies that have arisen as to the responsibility of the several Lords it is unnecessary to enter here. The Admiralty Board possesses, in fact, the character of a council, and its members can only be held responsible for their advice. It has even been contended that, in the circumstances, it should not be incumbent upon them to sign the navy estimates, and there have been instances in which the estimates have been presented to Parliament without the signature of certain Naval Lords. It is in any case obvious, as has been explained above, that the ultimate responsibility must always rest with the First Lord and the Cabinet, by whom the policy of the country is shaped and directed. In the report of the Hartington Commission to inquire into the civil and professional administration of the Naval and Military Departments, and the relation of these departments to each other and to the Treasury, the following recommendation occurs: "On the First Lord alone should rest the responsibility of deciding on the provision to be made for the naval requirements of the empire, and the existence of a council should be held in no degree to diminish that responsibility."

Two conditions primarily rule the determination as to the strength of the navy. They are, the foreign policy of the Cabinet, and on the ground of practical expediency, the amount of money available. "The estimates and strength of the navy," said Rear-Admiral Hotham before

the select committee on the navy estimates, 1888, "are matters for the Cabinet to determine." "Expense," said Sir Anthony Hoskins, "governs everything." The needs of the empire and financial considerations, as it is scarcely necessary to remark, may prove to be antithetical conditions governing the same problem, and in practice it follows that the Admiralty Board directs its operations in accordance with the views of the Government, but limited by the public funds which are known to be available. Such considerations suggest a practical limitation of responsibility, so far as the several Lords of the Admiralty are concerned, but it may be presumed to be their duty individually or collectively to place their views before the First Lord; and Lord George Hamilton told the select committee of 1888 that, if his colleagues should represent to him that a certain expenditure was indispensable for the efficiency of the service, he would recognize that all financial considerations should be put on one side. The commissioners reported that this was the only common-sense view of the matter, and that it was difficult to see on what other footing the control of navy expenditure, consistently with responsibility to Parliament, could be placed.

Two practical considerations are bound up with the shipbuilding programme—the carrying forward of the work in hand and the new construction to be begun, since it is absolutely necessary that proper provision should be made for the employment and distribution of labour in the dockyards, and for the purpose of necessary materials. Through the director of naval construction and the director of dockyards, the Controller is kept informed as to the progress of work and the amount of labour required, as also in regard to the building facilities of the yards. These matters, in a general way, must form a subject of discussion between the first Naval Lord and the Controller, who will report on the subject to the First Lord. The accountant-general, as the financial officer of the Board, will be called upon to place the proposed estimates upon a financial basis, and when the views of the Cabinet are known as to the amount of money available, the several departments charged with the duty of preparing the various votes will proceed with that work. The financial basis alluded to is, of course, found in the estimates of the previous year, modified by the new conditions that arise. There has been in past times a haphazard character in our shipbuilding programmes, but with the introduction of the Naval Defence Act of 1889, which looked ahead and was not content with hand-to-mouth provision, a better state of things has grown up, and, with a larger sense of responsibility, a policy characterized by something of continuity has been developed. Certainly the largest factor in the better state of things has been the growth of a strong body of public opinion as to the supreme value of the navy for national and imperial welfare. No Government could have carried forward the great work which has been accomplished for the British navy within the last ten years without the impulsion and the support of public opinion.

Another important and related matter that comes before the Board of Admiralty is the character and design of ships. The naval members of the Board indicate the classes and qualities desired, and it is the practice that the sketch-design, presented in accordance with the instructions, is fully discussed by the first Naval Lord and the Controller and afterwards by the Board. The design then takes further shape, and when it has received the final sanction of the Board it cannot be altered without the sanction of the same authority. A similar procedure is found in the other business of the Admiralty Board, such as shore-works, docks, and the preparation of offensive and defensive plans of warfare—the last being

a very important matter that falls into the operations of the Naval Intelligence Department, which has been described, though not with perfect accuracy, and certainly in no large sense, as "the brain of the navy." That department is under the direction of the first Naval Lord.

The shipbuilding programme may be described as the corner-stone of the executive business of the Admiralty, because upon it depends very largely the preparation of all the other votes relating to numbers, stores, victualling, clothing, &c. But if the Admiralty Board is responsible through the First Lord for the preparation of the estimates, it is also charged with the business of supervising expenditure. In this matter the financial secretary plays a large part, and is directed to assist the spending department of the Admiralty in their duty of watching the progress of their liabilities and disbursements. Some notes on Admiralty finance will be found below (parts iv., vii.). The shipbuilding votes set the larger machinery of the Admiralty in motion. The executive departments, except in regard to the hulls and machinery of ships and the special requirements of the director of works, do not make purchases of stores, that work resting with the director of navy contracts. Most of the important executive and spending branches are in the department of the Controller, and it will be well, while we are dealing with the material side of the navy, to describe briefly their character and duties. The civil branches of the navy tributary to the Controller are those of the director of naval construction, the engineer-in-chief, the directors of naval ordnance, of dockyards, and of stores, and the inspector of dockyard expense accounts. The first duty of the Controller is, as has been explained, in relation to the design and construction of ships and their machinery, and the executive officials who have charge of that work are the director of naval construction and the engineer-in-chief, whose operations are closely inter-related. A vast administrative stride has been made in this particular branch of the Admiralty. The work of design and construction now go forward together, and the Admiralty designers are in close touch with the work in hand at the dockyards—a condition which did not exist twenty-five years ago. This has been largely brought about by the institution, in 1883, of the royal corps of naval constructors, whose members interchange their duties between the designing of ships at the Admiralty and practical work at the dockyards. It is through the director of naval construction that many of the spending departments are set in motion, since he is responsible both for the design of ships and for their construction. It deserves to be noticed, however, that a certain obscurity exists in regard to the relative duties of the director of naval construction and the director of dockyards touching constructive works in the yards. The former officer has also charge of all the work given out to contract, though it is the business of the dockyard officials to certify that the conditions of the contract have been fulfilled. In all this work the director of naval construction collaborates with the engineer-in-chief, who is an independent officer and not a subordinate, and whose procedure in regard to machinery closely resembles that adopted in the matter of contract-built ships.

The director of naval ordnance is another officer of the Controller's Department whose operations are very closely related to the duties of the director of naval construction, and the relation is both intimate and sustained, for in the Ordnance Department everything that relates to guns, gun-mountings, magazines, torpedo apparatus, electrical fittings for guns, and other electrical fittings is centred. A singular feature of this branch of administration is that the navy long since lost direct control of ordnance matters,

through the duties connected with naval gunnery, formerly in the hands of the master-general of the ordnance, and those of the Board of Ordnance—a department common to the sea and land services—being vested in 1855 in the Secretary of State for war. A more satisfactory state of things has grown up through the appointment of the director of naval ordnance, taking the place of the naval officer who formerly advised the director of artillery at the War Office. Expenditure on ordnance has also been transferred from the army to the navy estimates, and a Naval Ordnance Store Department has been created. It cannot be said that the condition is yet satisfactory, nor can it be until the navy has control of and responsibility for its own ordnance. The assistant-director of torpedoes is an officer instituted at the Admiralty within recent years, and his duty is to assist the director of naval ordnance in all torpedo matters.

As to the operations of the director of dockyards little need be said here. (See DOCKYARDS.) This officer replaced the surveyor of dockyards in 1885, at about which time the inspector of dockyard expense-accounts was instituted. It is upon the director of dockyards that the responsibility of the Controller devolves in regard to the management of dockyards and naval establishments at home and abroad, and to the performance of work in these establishments, ship and boat building, maintenance, repairs, and refits. In this department the programme for work in the dockyards is prepared, as well as certain sections of the navy estimates.

We now come to the Stores Department, with the director of stores as its chief. This officer, about the year 1869, took over the storekeeping duties previously vested in the storekeeper-general. The Naval Store Department is charged with the custody and issue of naval, as distinguished from victualling and ordnance stores, to be used in naval dockyards and establishments for the building, fitting, and repairing of warships. It has, however, no concern with stores that belong to the Department of Works. The business of the director of stores is also to receive and issue the stores for ships of all classes in commission and reserve, and he deals with a vast array of objects and materials necessary for the fleet, and with coals and coaling. He frames the estimates for his department, but his purchases are made through the director of navy contracts. In practice the main business of the Stores Department is to see to the provision of stores for the navy, and to the proper supply of these at all the establishments, and for this purpose its officials direct the movements of storeships, and arrange for the despatch of colliers, the director being charged to be "careful to provide for His Majesty's ships on foreign stations, and for the necessary supplies to foreign yards." Another important business of the director of stores is the examination of the store accounts of ships as well as some other accounts. Although the director of stores is really in the department of the Controller, he is supervised in regard to the coaling of the fleet by the junior Naval Lord. The inspector of dockyard expense-accounts has been alluded to. He is the officer charged with keeping a record of expenditure at the dockyards and of supervising expense accounts.

IV. *The Matériel of the Navy—Recent Administration.*—Having now described the administrative system of the navy, taking the preparation of the shipbuilding programme as an illustration, it will be well here to recall the recent history of naval administration in that regard. The shipbuilding programme is the beginning of the practical work of administration, because the Government having shaped its policy and indicated its requirements and the possibilities that present themselves, the material elements of naval power are created, and the personal ele-

ments, with all that concerns the training of officers and men, follow according to the necessities implied by the existence of that matériel. This is not to say that the ship is more important than the company who are in her, but only that the matériel of the navy constitutes the conditions for which the personnel are embodied, organized, and trained. It will be obvious from what follows, in regard to the shipbuilding programmes of recent years, that the development of the fleet, conducted by the Admiralty under the authority of the First Lord and the Cabinet, has been largely influenced by the voice of public opinion. A Government in power has strong inducement to keep down expenditure and taxation, and the stimulus of a strong body of public opinion appears to be necessary in order to insure that the navy shall be maintained in adequate strength. This is a matter which cannot be overlooked in any account of naval administration. In the spring of 1870 Mr Childers assured Parliament that the navy was sufficient for any duty it was likely to be called on to perform—as did Lord Cardwell for the army. In June, when the Franco-German war broke out, £2,000,000 was voted to put the armed forces in a state of efficiency, although the war did not directly affect Great Britain.

At the time of the Russo-Turkish war great uneasiness was manifested in the United Kingdom as to the sufficiency of the navy, and on 25th January 1878 a vote of credit of £6,000,000 was passed by the House of Commons to enable the Admiralty to make good the deficiency.

The existing programme was pushed forward, and a number of ships were bought, but consistent policy was still absent from the proceedings. Again, when the estimates of 1884-85 were presented uneasiness still existed, and Lord Northbrook said in the House of Lords that it would be an extravagance to spend £2,000,000 in the construction of large ironclads, and that the great difficulty the Admiralty would have to contend with if they were granted £3,000,000 or £4,000,000 for the purpose referred to, would be to decide how they should spend the money. It is true that at the time the minds of naval constructors were not settled as to the type of vessel desirable, and that there were many fluctuations of opinion in regard to naval policy. But at about the same time alarm was spread by the action of Russia upon the Afghan frontier, in relation to what was known as the "Panjdeh incident," and Lord Northbrook introduced a special shipbuilding programme. He explained, in March 1885, that in the navy estimates for the year there would be an increase of £800,000 for building ships by contract and carrying out the programme announced in the previous December. In addition the navy estimates of the year showed the further increase of £700,000, making a total augmentation, exclusive of supplementary estimates, of about £1,500,000. The country had been profoundly moved by the political situation abroad, and from that time may be said to date the great expansion of the fleet which has taken

place since the introduction of the Naval Defence Act of 1889. A powerful agitation was conducted by the press, and at length the necessity of a great expenditure was recognized by the Government. In the previous year Lord Charles Beresford, being dissatisfied with the provision made for the navy, had resigned his seat at the Admiralty Board, proposing a programme of additional ships which he considered to be necessary. Many articles were contributed to the press, and a meeting was convened in the City of London by the Lord Mayor, so that pressure was put upon the Government and the Admiralty, and a five years' programme was introduced by Lord George Hamilton, then First Lord. As a ground of decision in regard to the naval strength required, the

*The Naval
Defence
Act, 1889.*

Admiralty, after the naval manœuvres of 1888, had directed three admirals—Sir William Dowell, Sir R. Vesey Hamilton, and Sir F. Richards—to furnish a report. They arrived at the following conclusion: "It will not be found practicable to maintain an effective blockade of an enemy's squadrons in strongly fortified ports by keeping the main body of the fleet off the port to be blockaded, without the blockading battleships being in the proportion of at least five to three to allow a sufficient margin for casualties, to which the enemy's vessels in a secure harbour would not be exposed, and the necessary periodical absence of a portion of the blockading squadron for the purpose of replenishing fuel, making good defects, &c. A still larger proportion might be necessary if the area to be covered by the blockaders was extensive." It may be said that this report was at the base of the Naval Defence Act programme and of those which have followed it, and it has constantly been appealed to by writers and speakers, though it is a question whether recent developments of foreign navies do not indicate the necessity of a larger proportion of British ships. The Naval Defence Act, 1889, 52 Vict. cap. 8, being "an Act to make further provision for naval defence and defray the expenses thereof," marked the beginning of a larger conception on the part of the Government and the Admiralty of the needs of the British empire, and it may be said to have formed the practical beginning of the existing efficient navy. Ships were in existence—the *Admiral* class, for example—of an earlier date, but it is nevertheless true that the vessels put in hand under the Naval Defence Act marked a real beginning. The preamble of the Act was as follows: "It is expedient that a sum not exceeding £21,000,000 be granted for the purpose of building, arming, equipping, and completing for sea vessels of Her Majesty's navy; and that it is expedient that a sum not exceeding £10,000,000 be issued out of the consolidated fund in seven years, ending the 31st of March 1896; and that a sum not exceeding £11,000,000 be issued out of the moneys to be provided by Parliament for the naval service during the financial years ending the 31st of March 1894." A subsequent measure supplemented the Act of 1889, and was described as the Naval Defence Act 1893, 56 & 57 Vict. cap. 45: "An Act to make further provision for the completion and equipment of ships under the Naval Defence Act 1889, and to amend that Act," and the new provision made was for a grant of moneys not exceeding £1,350,000. The programme of the Naval Defence Act was for the building of ten battleships, of which eight were of the first class, and displaced 14,150 tons, while two, which were then described as of the second class, but are now ranked of the first, were of 10,500 tons. The eight larger battleships built under the Act were the *Royal Sovereign*, *Empress of India*, *Hood*, *Ramillies*, *Repulse*, *Resolution*, *Revenge*, and *Royal Oak*, and the two smaller ships the *Centurion* and *Barfleur*. These are all ships of high freeboard, the larger ones with four 13.5-inch and the smaller with as many 10-inch guns in their barbetstes, and in the matter of protection they marked a great advance upon their predecessors. The Naval Defence Act also provided for the building of nine first-class cruisers—the *Royal Arthur* and the *Crescent* (7700 tons), and the *Edgar*, *Endymion*, *Gibraltar*, *Grafton*, *Hawke*, *St. George*, and *Theseus*, as well as thirty-three second-class cruisers. The second-class cruisers were to be of 3400 tons, but before the programmes could be carried out the dimensions of several of them were increased to 4360 tons. The end of the financial year 1894-95 saw the completion of five second-class cruisers and four torpedo gunboats, which brought to an end the work provided for under the Naval Defence Act. The vessels were soon completed for sea,

and most of them were commissioned for the manœuvres of 1895. The limit of five years, which had originally been fixed for the completion of these vessels, had been somewhat exceeded.

Meanwhile provision had been made in the programme of 1892-93 for the laying down of the battleship *Renown*, displacing 12,350 tons and lying midway between the *Royal Sovereign* and *Centurion* classes, as well as for certain destroyers and other torpedo craft. Naval programmes, 1892-1902. It was on 23rd June 1893, off the coast of Tripoli, Syria, that the lamentable catastrophe occurred in which the *Victoria*, flagship of Sir George Tryon, commander-in-chief in the Mediterranean, was lost through collision with the *Camperdown*. This incident, combined with a strong feeling that after the close of the principal work of the Naval Defence Act no adequate provision had been made, caused Earl Spencer, then First Lord of the Admiralty, to introduce a new programme. In December 1893 Sir William Harcourt had told the House of Commons that the professional advisers of the Admiralty—meaning the Naval Lords—were of opinion that the navy was in a satisfactory state, and that its supremacy was for the moment absolute, and added that he would undertake to say that the "superiority of the British navy was never so great as it is now." It was commonly believed that the Naval Lords thereupon resolved to resign, but two days later Sir William Harcourt made a statement which modified the impression he had given. The agitation of that time materially strengthened the hands of Lord Spencer, and the programme of 1893-94 provided for the laying down of two new battleships—the *Majestic* and *Magnificent*—of 14,900 tons, afterwards first and second flagships of the Channel squadron, as well as three second-class cruisers—the *Talbot*, *Eclipse*, and *Minerva*—and two sloops. Two first-class cruisers—the *Powerful* and *Terrible*—belong to the same year, and after being deferred were given out to contract in December 1893. They were the first large vessels of the British fleet to be provided with water-tube boilers, these being of the Belleville type. The shipbuilding programme of 1894-95 included seven battleships, six cruisers of the second class, and two sloops. The battleships were of the *Majestic* class, and received the names of *Prince George*, *Victorious*, *Cæsar*, *Hannibal*, *Illustrious*, *Jupiter*, and *Mars* (14,900 tons). The second-class cruisers were the *Venus*, *Diana*, *Dido*, *Isis*, *Juno*, and *Doris*, displacing 5600 tons. All these were built by contract, as was the case with two of the battleships of that year. The shipbuilding work put in hand under this programme gave full occupation to the building yards, and the constructive scheme embodied in the estimates of 1895-96 did not include any battleships. There were four first-class protected cruisers of 11,000 tons, resembling in various ways the *Powerful* and *Royal Arthur* classes—the *Diadem*, *Andromeda*, *Europa*, and *Niobe*—all provided with Belleville boilers, and calculated for a speed of 20.5 knots; four second-class cruisers of 5750 tons—the *Arrogant*, *Furious*, *Gladiator*, and *Vindictive*; two third-class cruisers of 2135 tons—the *Pelorus* and *Proserpine*; and twenty torpedo-boat destroyers. The work conducted under the programme so far described was carried out with great rapidity. The *Majestic* and *Magnificent*, built respectively at Portsmouth and Chatham, were commissioned within twenty-two and twenty-four months from the laying of the keel, thus surpassing all previous records, and the *Prince George* at Portsmouth and the *Victorious* at Chatham maintained this rapidity of construction. Moreover the progress made with these vessels did not interfere with the maintenance of the progress intended either on new shipbuilding or in keeping up the

sea-going and fighting efficiency of ships in reserve or commission. Good progress was also attained with the remaining five ships of the *Majestic* class, though in subsequent years, owing to strikes in the engineering trade and some other circumstances, the work was much impeded. The programme of 1896-97 included five battleships, of which three—the *Goliath*, *Canopus*, and *Ocean*—were built in the dockyards, and two—the *Albion* and *Glory*—by contract on the Thames and the Clyde. They are of a new class, displacing 12,950 tons, standing midway between the *Renown* and the *Majestic*. The programme also included four first-class protected cruisers of the *Diadem* class (11,000 tons)—the *Spartiate*, *Argonaut*, *Amphitrite*, and *Ariadne*; three second-class cruisers of 5600 tons—the *Hermes*, *Highflyer*, and *Hyacinth*; six third-class cruisers of 2135 tons—the *Pomone*, *Prometheus*, *Pegasus*, *Pyramus*, *Pactolus*, and *Perseus*; and twenty-eight torpedo-boat destroyers. Of the first-class cruisers, the *Spartiate* was laid down at Pembroke, and the others in private yards. The vessels under construction during this year comprised thirteen battleships, ten first-class cruisers, sixteen second-class cruisers, seven third-class cruisers, and a number of destroyers; and the expenditure involved considerably exceeded that incurred in any previous financial year, and the numbers and type of the new ships laid down were exceptional. The progress made was in many ways good, the *Mars* and *Jupiter*, for example, being delivered by the contractors five months within the contract date. Some of the ships were, however, greatly retarded by the dispute in the engineering trade. The *Cæsar*, *Illustrious*, and *Hannibal* were delayed, and some of the ships of the *Canopus* class, though rapidly pushed forward until the engineering dispute began, were, owing to the non-delivery of structural portions, much retarded. Progress with certain of the cruisers was also impeded. In the shipbuilding programme of 1897-98 four battleships were included—the *Vengeance*, of the *Canopus* class, built at Barrow, and the *Formidable*, *Implacable*, and *Irresistible* (*Majestics* with some improvements), constructed in the dockyards. The programme also included three third-class cruisers, two sloops, four gunboats, two torpedo-boat destroyers, and a new royal yacht, which was built at Pembroke. In addition, Mr Goschen, then First Lord, announced in July 1897 that in consequence of the proposed additions to the navies of foreign Powers, he had received an additional sum of £500,000 from the chancellor of the exchequer, wherewith it was proposed to begin the construction of four armoured cruisers of an entirely new design, which, it was said, would be capable both of commerce protection and of taking their place in the line of battle. These were the *Cressy* and *Aboukir*, built at Glasgow, the *Hogue* at Barrow, and the *Sutlej* at Clydebank—all displacing 12,000 tons. This extensive programme was very seriously affected by the prolonged labour disputes, which lasted from July 1897 until February 1898, and Mr Goschen confessed that the Board was unable to foresee the exact amount by which the anticipated expenditure on new constructions would fall short. The difficulties arising from the labour dispute affected the production of machinery, gun-mountings, armour, and almost every important class of material, and in the dockyards the work was delayed by the inability of the contractors to deliver the material they had undertaken to supply. The commencement of the armoured cruisers was also delayed by the introduction and trial of new types of 12-inch and 6-inch guns. Nevertheless the estimates of 1898-99 proposed to build three battleships of 15,000 tons and of the *Formidable* class—the *London*, *Venerable*, and *Bulwark*; and to put in hand also two

armoured cruisers of the *Cressy* class—the *Euryalus* and *Bacchante*; and two others—the *Drake* and *King Alfred*—of a still larger type, displacing 14,100 tons, as well as four sloops. The year 1898-99 was also marked by the introduction of a supplementary shipbuilding programme. It was explained by the First Lord, in July 1898, that the programme at first presented was considered adequate at the time, and was based on the principle that the British navy must be equal in number, but superior in power, to the fleets of any two countries. Mr Goschen stated that it was impossible to conceal the fact that the action of Russia, and the programme on which she had entered, was the cause of this further strengthening the fleet. Mr Goschen's explanation was enforced in these words: "What, then, is our position? We know of six Russian battleships to be laid down this year, including one already begun. We have now verified where those six ships are to be built. Of those I took two into account in my original estimate, so that the balance against us was four. Accordingly, I must ask the House to sanction four battleships beyond my original estimate. The new Russian programme also provides for four cruisers from the commencement of this year, and we propose to commence an equal number—that is to say, four cruisers in addition to those provided for already." The supplementary programme, therefore, provided for the laying down of four battleships and four armoured cruisers, as well as twelve destroyers, and the total liability involved was about £8,000,000, to be spread over about three and a half years. The four new battleships were the *Duncan*, *Cornwallis*, *Exmouth*, and *Russell*, all built by contract, displacing 14,000 tons, and intermediate in size between the *Formidable* and *Canopus* classes with superior speed and thinner armour, the latter being due to improved processes of steel-production. The armoured cruisers were the *Leviathan* and *Good Hope*, both of the *Drake* class (14,100 tons), and the *Bedford* and *Monmouth* of a smaller type (9800 tons). Shipbuilding progress was still impeded, work being much disarranged owing to the unprecedented activity in mercantile shipbuilding which followed the labour dispute, and serious delay resulted from the inability of the shipbuilding contractors to procure the necessary materials. The ships could not thus be laid down nor carried forward so advantageously as had been hoped, and further delay occurred owing to the introduction of the Krupp process of armour, which made necessary the reconstruction of steel-producing plant. The programme of 1899-1900 included two other battleships—the *Montague* and *Albemarle* (14,000 tons)—of the *Duncan* class, and two armoured cruisers—the *Kent* and *Essex* (9800 tons)—of the *Bedford* class, all to be built in the dockyards, as well as three smaller cruisers, two sloops, and two first-class torpedo boats. Once more it proved that abnormal activity in shipbuilding and engineering seriously affected building progress, and checked expenditure on ships, machinery, and armour. Delay in the delivery of material, difficulties in securing adequate numbers of workmen, and other circumstances caused the aggregate earnings on contract work to fall short of the estimated amount by about £1,400,000, although the estimate had been calculated on the basis of actual earnings in past years of ships of similar character, and on close investigation of the possible output of armour. Progress in the dockyards was also impeded, and was further affected by the fact that a large number of the ships were designed for exceptionally high speed, and were therefore to be provided with propelling machinery of great power. The shipbuilding programme of 1900-1 included two battleships—the *Queen* and *Prince of Wales*; six first-class armoured

Delays in construction.

cruisers—the *Cornwall*, *Suffolk*, *Cumberland*, *Lancaster*, *Donegal*, and *Berwick*; one second-class cruiser (an improved *Hermes*), two sloops, two light-draught gunboats, and two torpedo boats. The programme of 1901-2 included three battleships, six armoured cruisers, two third-class cruisers, ten destroyers, five torpedo boats, two sloops, and five submarine boats. Shortly after the estimates were presented the Admiralty Boiler Committee made an interim report, in which the Belleville boiler was condemned, and a trial of other water-tube types recommended.

It may be useful to add a note concerning the spending of the money. Within the Controller's Department, as has been explained, are centred the more important spending branches of the Admiralty. While the work of designing ships and preparing plans is in progress, the director of stores, the director of dockyards, and other officials of that department concerned are making preparation for the work. The necessary stores, comprising almost every imaginable class of materials, are brought together, and the director of stores is specially charged to obtain accurate information in regard to requirements. He is not, however, a purchasing officer, that work being undertaken by the director of navy contracts, who is concerned with the whole business of supply, except in regard to hulls and machinery of ships built by contract, and the special requirements of the director of works. At the same time, the civil departments of the Admiralty being held responsible for the administration of the votes they compile, it is their duty to watch the outlay of money, and to see that it is well expended, the accountant-general being directed to assist them in this work. The system is closely jointed and well administered, but it possesses a very centralized character, which interferes to some extent with flexible working, and with the progress of necessary repairs, especially in foreign yards. In so far as ships given out to contract are concerned (and the same is the case in regard to propelling machinery built by contract), the director of navy contracts plays no part, the professional business being conducted through the Controller of the navy, who is advised thereon by the director of naval construction and the engineer-in-chief. The work conducted in private establishments is closely watched by the Admiralty officials, and is thoroughly tested, but, *mutatis mutandis*, the system in regard to contract-built ships is practically the same as that which prevails in the dockyards.

V. *Personnel*.—No work of the Admiralty is more important than the supply of trained officers and men to the fleet. The provision of these in adequate number, the organization of the training service, the constitution of the reserve, and many other questions connected with the pay, promotion, and retirement of officers and men impose a great duty upon the Admiralty Board. The work mainly lies in the province of the second Naval Lord, who has charge of the work of manning the fleet, and educating and training the personnel, together with the affairs of the royal marine light infantry and the royal marine artillery. Within his purview are all training establishments, including those for engineer students, the naval colleges, and the royal marine schools. The First Lord of the Admiralty has special charge of promotions and removals of naval and marine officers to or from the service, and of the appointments of flag officers, captains, all officers to command ships, commanders to the coast-guard, superior officers to the medical service, staff appointments to the royal marines, and civil appointments and promotions, except where these fall under the Controller and the Civil Lord. The first Naval Lord appoints commanders (second in command), and the second Naval Lord navigating officers and lieutenants,

sub-lieutenants, midshipmen, cadets, engineer officers, and others, while the appointment of chaplains, naval instructors, junior medical officers, paymasters, and other officers of the accountant branch falls to the junior Naval Lord. The increase of the matériel of the fleet has led to large additions being made to the numbers of officers and men, and the conditions of service have been in some ways modified. The general regulations are published in the *Quarterly Navy List*, so that it is unnecessary to refer to them here. The great scarcity of lieutenants caused the Admiralty, in the year 1895, to institute a supplementary list of naval lieutenants and sub-lieutenants, who were appointed under special conditions from the mercantile marine, and are not promoted beyond the rank of lieutenant unless for distinguished service, but are retired at forty-five years of age. Changes have also been introduced in the conditions and service of the royal naval reserve, and it may be said that the system of training is still under trial and that it is not yet definitely established. The number of officers, seamen, boys, coastguard, and royal marines borne on the books of His Majesty's ships and at the royal marine divisions are fixed yearly by vote A of the navy estimates. The following table shows the annual increase in the number in these ranks and ratings during the ten years 1890-1900:—

Year.	Total Number borne at end of Year.	Increase during Year.
1890-91	67,748	1764
1891-92	71,423	3675
1892-93	74,429	2997
1893-94	77,976	3556
1894-95	83,117	5141
1895-96	88,674	5557
1896-97	94,376	5702
1897-98	100,052	5676
1898-99	106,002	5950
1899-1900	111,019	5017

The total force voted for the year 1900-1 was 114,880, being an addition of 220 officers, 3050 petty officers and seamen, 150 engine-room staff, 200 miscellaneous ratings, 300 marines, and 320 apprentices (artisan ratings), making in all an addition of 4240. A further increase of 3745 was authorized in the next year. The number of officers is being increased under a scheme extended gradually over a certain number of years, and it was announced in 1899 that the flag officers would be increased from 68 to 80, the captains from 208 to 245, the commanders from 304 to 360, and the lieutenants from 1150 to 1550. Increases were also instructed to be made in the other branches of the service. The additions made to the matériel of the navy had outrun the provision made for the supply of officers, and the list of supplementary lieutenants was increased to tide over the interval which would elapse before a sufficient supply of executive officers trained up in the service could be produced in the ordinary course, it being easier to build ships than to train those required to man them.

Except for the list of supplementary lieutenants and sub-lieutenants which has been referred to, all executive officers of the navy enter as cadets upon the nomination of the First Lord of the Admiralty (who also nominates assistant clerks for the accountant branch) and are trained in the naval establishment now located in the *Britannia* at Dartmouth, which is about to be transferred to a building ashore. A few nominations are given to the sons of colonial gentlemen and of naval and military officers for special reasons of service, and in particular cases a few youths are entered from the *Worcester* and *Conway* training-ships of the mercantile marine. Latterly, a new arrangement as regards the entry and training of cadets

has been instituted, and came into force in the year 1897-98. The result is gradually to raise the age for entering by one year, and to shorten the course of instruction in the *Britannia* to about sixteen months, and cadets are now entered three times a year instead of twice. The effect of this change is that about 190 cadets pass through the *Britannia* yearly instead of 125, as was the case formerly, and that 170 sub-lieutenants will be ultimately produced annually instead of 116. The question of a limited competition as compared with an open one has been much discussed. It has been argued that it is anomalous to have open competition for some branches and limited competition for others, and that the exercise of the right of nomination by the First Lord is liable to be influenced by political considerations.¹ After passing a certain time afloat, or in the case of the most successful boys at the date of their leaving the *Britannia*, the cadets are appointed midshipmen, and upon gaining the age of nineteen and completing three and a half years' service afloat as midshipmen, they may pass for sub-lieutenants, the examination being in seamanship, navigation, torpedo, gunnery, and pilotage. As an acting sub-lieutenant the young officer proceeds to the Royal Naval College, Greenwich, where his navigation and pilotage examination takes place, and he then passes to the gunnery and torpedo establishments at Portsmouth, where upon passing the examination he is confirmed in the rank of sub-lieutenant.

Promotion to lieutenant depends upon the class of certificates obtained at these examinations.

Promotion of officers. Thus, five first-class certificates and promotion-marks secure the promotion of the sub-lieutenant after six months from the date of seniority in that grade, five ordinary first-class certificates after twelve months, and so on down to twenty-seven months as sub-lieutenant, after which promotion is only by seniority. The duties of a lieutenant afloat are many and various, and include the charge of watches and of a division of men, with drill at the guns. A certain number of lieutenants specially qualify in gunnery, torpedo, and navigation, and are appointed to ships to act in the capacity of specialists in these matters. Above the rank of lieutenant promotion is by selection, twice a year, according to the needs of the service, a certain number of lieutenants being promoted to the rank of commander. Lieutenants are also promoted to commander from the royal yacht and for distinguished service. Before this time, however, a separation of duties may have occurred, for it is open to a certain number of lieutenants, under particular conditions, to be transferred to the coastguard, and to forego further chances of promotion. Captains are promoted by selection from the commanders' list, and captains, like officers of every other branch, are retired under the limit of age applicable to their rank. Their promotion to flag rank is by seniority, and depends upon the vacancies arising in the rear-admiral's list. In the same way rear-admirals rise to vice-admirals and admirals by seniority, but are promoted "admirals of the fleet" by selection.

The position and pay of officers of the engineer branch has steadily improved during recent years. They enter between the ages of fourteen and seventeen, mostly by competitive examination, though a few nominations remain with the Admiralty. The course at the Royal Naval Engineers' College at Keyham is of four or five years. The most successful students at the final examinations go to the Royal Naval College, Greenwich, for a further course, and the most successful of these may be appointed to the royal corps of naval constructors.

The less successful students are appointed probationary assistant engineers, and are confirmed in the rank after a period of service. Assistant engineers may pass for engineers after three years' service, and are eligible for promotion after five years' service. Promotion to chief engineer is by seniority as vacancies occur, and further promotion to inspector of machinery is by selection, and to chief inspector of machinery by seniority, these last two ranks being for officers appointed to various establishments at home and abroad.

The entry of accountant officers is like that of cadets, by nomination and limited competition, and under recent regulations the entry is made between the ages of seventeen and eighteen. The successful candidates are assistant clerks, passing after twelve months as clerks, and at the age of twenty-one, upon examination, become assistant paymasters. Promotion to paymaster is by seniority, and by qualifying time afloat there is promotion to staff-paymaster, and fleet-paymaster. Admirals' secretaries are selected from the ranks of assistant paymasters and paymasters.

Officers of the medical branch must be qualified under the Medical Act, and upon examination the candidates are appointed surgeons in the royal navy, and are specially trained at Haslar Hospital. After twelve years' full-pay service surgeons are advanced to the rank of staff-surgeons, and after a further period the rank of fleet-surgeon is gained. The deputy inspector-general is selected from the fleet-surgeons' list, and the inspector-general of hospitals and fleets from among the deputy-inspectors.

Chaplains are appointed to the fleet by the Admiralty after examination. They must have been ordained deacons or priests in the Church of England, or be of the same orders "by the lawful authority of one of the churches within the realm of Great Britain and Ireland which are in communion with the Church of England." In addition to his clerical duties the chaplain may act as naval instructor, but there is a special branch of naval instructors who are found qualified after attaining at least a "senior optime" at Cambridge, a second class in the final mathematical schools at Oxford, or junior moderator in pure or mixed mathematics at Dublin. These officers are further trained at Greenwich, and it is only after passing a qualifying examination that chaplains can also undertake the duties of naval instructors.

The royal naval reserve is an extremely popular force composed of officers (and others) of the mercantile marine—lieutenants, sub-lieutenants, senior engineers, and engineers, assistant engineers, and midshipmen. These officers are entered by the Admiralty upon certification by the Board of Trade, under regulations which are found in the *Quarterly Navy List*. Many of them undergo twelve months' training in ships of the fleet, and all those on the active list are required to drill on board one of the royal naval reserve drill-ships for a certain number of days yearly. The number of those on the list who had served or were serving was 267 in April 1900. Vacancies for executive officers of the reserve are filled as soon as they occur, and many qualified candidates present themselves for every vacancy. In 1898-99 provision was made for increasing the executive officers' list by 100, and the establishment of engineer officers of the royal naval reserve has been fixed at 400. The fleet reserve is a new organization devised to secure the retention of time-expired men on a system analogous to that of the army reserve.

The royal marines (*q.v.*), including the royal marine artillery and the royal marine light infantry, the former with their headquarters at Eastney, and the latter with their divisions at Chatham, Portsmouth, and Plymouth, are an extremely fine body of men, who serve alternately

¹ See appendix to the *Life of Admiral Lord C. Paget*, who was for six years parliamentary secretary of the Admiralty.

afloat and ashore. Candidates for commissions enter through the Civil Service Commissioners' examination at the Royal Military Academy at Woolwich, and upon passing out as second lieutenants the officers proceed to the Royal Naval College, Greenwich, after which there is training at the gunnery establishment at Portsmouth. In the case of the light infantry the training is similar, though there are some differences in procedure. A marine officer on board ship is in command of all marines in their distinct duty as such, but he cannot assume any naval command whatever, unless ordered to do so by the senior naval officer.

Details in regard to qualifications, pay, emoluments, and duties, may be found in the *Admiralty Instructions* and the *Quarterly Navy List*.

We may now turn from the officers to the men. Boys are entered in the training-ships between 14½ and 16½ years of age, and they undergo a course of instruction to qualify them for seamen, having on entry

Men.

signed an agreement to serve for twelve years from the age of 18, after which they can claim their discharge. When the course of training in the training-ships and brigs is sufficiently advanced the boys proceed on active service. Many boys are periodically drafted to the ships of the channel squadron, and there become ordinary seamen. The next rating to which men rise by service and good conduct is that of able seamen, and the various ratings of petty officers to that of chief petty officer follow. A certain proportion of men may become warrant officers (gunners, boatswains, &c.), a most valuable class of men, and these may rise to commissioned rank in the case of special gallantry against the enemy. Pensions are granted at the age of forty to seamen who have served for twenty-two years from the age of eighteen, according to conduct, ability, and advantage. Stokers are entered direct from the shore, serve some time in the steam reserve to be taught their drill and learn the discipline of the service, and go out on steam trials before being sent to a sea-going ship. Like the seamen they can rise from petty officer to warrant officer, a rank which gives a pension to the widow. The artificer class, which comprises blacksmiths, armourers, plumbers, carpenters, &c., have to pass an examination in their trade before being sent to sea-going ships. As is the case with officers, there may come a time when the petty officer may think it desirable to join the coastguard, which gives him duties on shore, but places him only in the rank of able seaman, while his gunnery and torpedo pay are stopped.

Allusion has been made to the officers of the royal marine forces. The men are enlisted for twelve years, and the service may be extended to twenty-one years. The recruit receives his first training at the depot at Walmer and may volunteer for the artillery branch in which the pay is better, and be transferred to it upon fulfilling the conditions. His duties ashore are those of a soldier, but when the time comes he is drafted for service afloat, and his duties then are in many respects analogous to those of the seamen. The royal marines, both of the artillery and light infantry branches, are an extremely fine body of men who have never failed to do good service when called upon, and the force has been largely increased within recent years. The average height of the men on entry has lately ranged from 5 feet 7½ inches to 5 feet 8 inches for the royal marine artillery, and from 5 feet 5½ inches to 5 feet 6 inches for the royal marine light infantry. The numbers of the corps are being steadily increased, and in the year 1901-2 there was a further addition to the force of 1000 men. The marines—their barracks, drill, and books—are inspected by the deputy adjutant-general of royal marines,

and their discipline is entirely under him, nor can they be sent away from their headquarters except by orders from the Admiralty. For garrison and field duties they are, when their naval duties so permit, under the general commanding the forces at their headquarters.

In the year 1899, at the commencement of the South African war, the masted training squadron which had been employed for the training of the boys of the seamen class, as well as of young officers, was replaced by a squadron composed of modern cruisers. This circumstance led to a discussion concerning the right system of training boys for service afloat. The question had been debated before, but in June 1900 Mr J. R. Thursfield read a paper upon the subject before the Royal United Service Institution, which was followed by an important discussion. The argument of the lecturer was that, though masted ships are no longer used in the navy, the training or discipline of masts and sails was well adapted to educe those qualities of alertness, readiness, quickness of eye, and rapidity of decision which are universally thought essential in seamen. On the other hand, a large number of naval officers were of opinion that the system implied by the existence of the small training squadron of masted vessels had given anything but satisfactory results. One after another various admirals who had lately commanded fleets, or who were then in command, testified to the need of some system of training which would restore the type of officer and seaman which they affirmed to be disappearing. The majority of these were of the opinion that no mere resuscitation of a training ship squadron of four-masted vessels would remedy the evil, while some ridiculed the idea of attempting to revive what they looked upon as dead and buried. It was very noteworthy, on the other hand, that some young officers appeared as stout advocates of the old system of training. In short, the discussion revealed the existence of two schools of thought on this important matter, and on either side were ranged officers of equal rank and experience. There was a consensus of opinion that something was needed for the training of the fleet, but a wide divergence of view was revealed as to what that something should be. It may be worth while to remark that the men of the naval brigade on the Benin expedition under Sir Harry Rawson, and those lately employed in South Africa and China, showed no deterioration in the characteristic handiness of the seaman.

VI. *Mobilization of the Fleet.*—By the mobilization of the fleet is meant the placing of naval resources upon a war footing, in readiness in all material and personal respects for hostile operations. It is obvious that this is the real crown and completion of the work of the Admiralty Board, and that there can be no department or branch which is not in some way concerned in it. The work of mobilization falls chiefly within the province of the first Naval Lord, and the mobilization branch of the Naval Intelligence Department is his agency. The essence of the work of that branch is described as "preparation for war," and it is concerned with the preparation of plans for organization, basing much of its work upon the information gained by the Foreign Intelligence Branch. The Naval Intelligence Department is a consultative office in the department of the first Naval Lord. But of course the second Naval Lord, who is chiefly concerned with the manning of the fleet, including the coastguard and the royal naval reserve, has a very large share in the duties of mobilization. The same may be said of the Additional Naval Lord and Controller, who is charged with all that concerns the matériel of the fleet, and again of the junior Naval Lord, whose duties are largely in the matters of

transport and auxiliary services. A large amount of information concerning mobilization—as indeed concerning all other naval subjects—will be found in *The British Fleet*, by Commander Charles N. Robinson, R.N., from which some of the following notes are taken. He remarks that mobilization is the point to which everything naval tends. It is the duty of the Admiralty to provide ships in efficient condition, with ammunition, coal, stores, and supplies, complete in every material respect—this implying of course adequate naval bases and coaling stations—and the mobilization of the personnel is the bringing of every man in due time to the ship and the duties for which he is appointed. The mobilization for the naval manœuvres is only a partial operation, for a complete mobilization would dislocate our sea-faring life in a manner that would be justifiable only by actual war. Thus, the auxiliary cruisers of the mercantile marine are not mobilized, nor the pensioners, nor the men of the royal naval reserve, though large numbers of the latter are, of course, afloat during the manœuvres.

The Admiralty is the central authority which sets the operation of mobilization in motion, but the duties involved fall to the naval commanders-in-chief at the ports and to the admiral superintendent of naval reserves. "These high and important functionaries are collectively as the brain of the maritime body in direct communication, through various active sub-centres, with its outermost limits. From them emanate the instructions which give effect to the order to mobilize." The first step is to complete in any details the complements of the ships actually in commission, and in practice young officers from Greenwich and other training establishments are attached to them. By a recent arrangement, however, the reserve squadron, consisting of the coastguard and the portguard ships at the various ports, is maintained with complete complements, and assembles periodically for training. The order to mobilize sets in motion many officers and men of the coastguard, and opens the gangways and doors of the training establishments, depôts, barrack, and harbour ships. From these come the seamen, gunners, torpedo men, signalmen, and stokers, who have been undergoing special courses, as well as the boys from the training-ships, the men who have had charge of machinery of ships in reserve, and, indeed, all classes of men required for ships commissioned, who are effective at the various quarters.

The arrangements made are admirably complete, and every man as he leaves his ship or depôt is provided with a card indicating his ship, station, and duties, so that he knows exactly where he is to go and what to do, and he falls into the plan precisely in the place which the careful paper scheme has provided for him. In this way the ships in the first division of the fleet reserve are provided with complements. These are the ships lying at the dockyards in every respect complete except for their crews, officers, stores, and ammunition. Meanwhile, the various victualling and store departments have been actively engaged in supplying every detail necessary for the ships, whose complements are completed by the embarkation of non-continuous service men, such as stewards and cooks. This is the point at which the annual mobilization generally stops short. But in case of hostilities it would, of course, go much further. Then the superintendent of naval reserves would be charged with the duty of supplying successive contingents of men to the naval ports to take the place of those sent afloat, these contingents to embark in their turn in the ships brought forward for commission, and to be succeeded again by others, according as the need arose. This work would begin from the headquarters of the coastguard divisions at Harwich, Hull,

Queensferry, Greenock, Kingstown, Limerick, Holyhead, Portland, and Southampton. The officers and men of the coastguard would go afloat comparatively early in the operations, and, in fact, a number of them go to sea annually during the manœuvres. Meanwhile, the officers and men of the royal naval reserve and the pensioners would have been set in motion to their respective drill-ships and barracks, and having been embodied would be converged upon the special naval ports where their services were required. In this way the ships in other classes of the reserve would receive their complements, as well as the auxiliary cruisers taken up from the merchant marine. As Commander Robinson remarks: "It is impossible to say where, in a great national crisis, the mobilization of men would end; for all the sea-faring manhood of our islands, all our artisan population—boilermakers, engine-fitters, electricians, engineers, carpenters, and a host of others, would render their best in the empire's need." The work would not end with the provision of complements for the ships, and a hundred other considerations would occupy the mobilizing authorities. They would be engaged in passing men through the special training ships to form the eventual complements of ships, or to replace those killed in action, and they would also have to supply efficient men for the signalling stations and for other duties.

A word has been said about the material requirements of the fleet upon mobilization. These are largely centred in the branches of the director of stores and the director of victualling. The former is concerned with the supply of a vast array of objects and necessaries, including coal, boats, oil, rope, candles, paint, varnish, and a host of other things. Adequate supplies are kept at the depôts, and the work of replenishment in case of mobilization would go forward steadily. The director of victualling being responsible under the junior Naval Lord for regulating the proper supply, care, and preservation of all victualling and clothing stores for the fleet, including mess-traps and seamen's utensils, and having charge of the victualling yards and depôts, maintains constantly adequate quantities at the various stations; and it may be useful to say that the chief victualling yard at home is that at Deptford, the others being at Portsmouth and Devonport, with a smaller establishment at Haulbowline (Queenstown), while there are depôts abroad at Gibraltar, Malta, Halifax, Bermuda, Jamaica, the Cape of Good Hope, Trincomalee, Hong-Kong, Esquimalt, Bombay, Ascension, Coquimbo, and Sydney. All these, of course, are supplied with a great quantity of stores that would play a most important part during a complete mobilization of the fleet.

VII. *Naval Finance: The Accountant-General's Department.*—The subject of naval finance is one of great complexity and of vast importance. The large sums of money with which the Admiralty deals both in the way of estimates and expenditure, amounting recently to about £30,000,000 annually, implies the existence of the great organization which is found in the department of the accountant-general of the navy. Under the authority of the First Lord, the parliamentary and financial secretary is responsible for the finance of the Admiralty in general, and for the estimates and the expenditure, the accounts and the purchases, and for all matters which concern the relations of the Admiralty to the Treasury and to other departments of the Government; and in all the practical and advisory work the accountant-general is his officer, acting as his assistant, with the director of naval contracts who, under the several Lords, is concerned with the business of purchase.

The organization of the accountant-general's department

has undergone many changes, and the resulting condition is the outcome of various modifications which have had for their purpose to give to this officer a measure of financial control. There have been various views as to what the duties of the accountant-general should be. After the reorganization of the Admiralty by Sir James Graham in 1832, the accountant-general was regarded as a recording and accounting officer, wholly concerned with receipt and expenditure. His duties were limited to the auditing of accounts, payments, and expenditure generally. Owing to changes effected in 1869, which made the parliamentary secretary, assisted by the Civil Lord, responsible for finance at the Admiralty, bringing the naval and victualling store departments into his charge, the accountant-general was invested with the power of criticizing these accounts financially, though he did not as yet possess any financial control, and the position was little changed by fresh rules made in 1876. It was not until 1880 that the powers of the accountant-general were enlarged in this direction. It was then ordered that he should be consulted before any expenditure which the estimates had not provided for was incurred, and before any money voted was applied to other purposes than those for which it was provided. The effect of this order was not happy, for the accountant-general could not undertake these duties without setting up friction with the departments whose accounts he criticized. It was contemplated by the Admiralty in 1885 to make the accountant-general the assistant of the financial secretary, and to raise him to the position of a permanent officer of finance instead of being an officer of account invested with imperfect authority in the direction of control. A select committee of the House of Commons reported that the accountant-general possessed no financial control over the departments, and that there was an urgent need for establishing such a control. At the time the position of that officer did not enable him to exercise any sufficient general supervision over expenditure, and there was no permanent high official expressly charged with finance. Accordingly, after being submitted to a departmental committee, a fresh arrangement was made in November 1885, whereby the accountant-general, under the authority of the financial secretary, was given a direct share in the preparation of the estimates. His written concurrence was required before the final approval of the votes, and each vote was referred to him for his approval or observations, and he was to exercise a financial review of expenditure and to see that it was properly accounted for. He became, in fact, "the officer to be consulted on all matters involving an expenditure of naval funds." It was believed that economical administration would result; but much opposition was raised to the principle that was involved of submitting the proposals of responsible departments to the inexpert criticism of a financial authority. Mr Main, assistant accountant-general, stated before the Royal Commission on Civil Establishments, 1887, that the effect had been to develop a tendency to withhold information or to afford only partial information, as well as to cause friction when questions were raised affecting expenditure, accompanied by protests, even in those cases in which these questions were manifestly of a legitimate character. The result was discouraging, and in the opinion of Mr Main had done much to weaken financial control and to defeat the purpose of the order. It is unnecessary to detail the various changes that have been made by the institution of dockyard expense accounts in the department of the Controller, and by various other alterations introduced. The Treasury instituted an independent audit of store accounts which greatly affected the position of the accountant-general, and the Royal Commission on Civil

Establishments reported that the Board of Admiralty were of opinion that they could dispense with the accountant-general's review altogether. The commission was, however, of opinion that the accountant-general should be the permanent assistant and adviser, on all matters involving the outlay of public money, of the financial secretary.

The operations of the accountant-general are now conducted in accordance with the Order-in-Council of 18th November 1885, and of an office memorandum issued shortly afterwards. He thus acts as deputy and assistant of the parliamentary and financial secretary, and works with a finance committee within the Admiralty, of which the financial secretary is president and the accountant-general himself vice-president. The duties of the department are precisely defined as consisting in the criticism of the annual estimates as to their sufficiency before they are passed, and in advising the financial and parliamentary secretary as to their satisfying the ordinary conditions of economy. The accountant-general also reviews the progress of liabilities and expenditure, and in relation to dockyard expenditure he considers the proposed programme of construction as it affects labour, material, and machinery. He further reviews current expenditure, or the employment of labour and material, as distinguished from cash payments of the yard, as well as proposals for the spending of money on new work or repairs of any kind for which estimates are currently proposed. The accountant-general's department has three principal divisions: the estimates division, the navy pay division, and the invoices and claims division. In the first of these is the ledger branch, occupied with the work of accounts under the several votes and sub-heads of votes, and with preparing the navy appropriation account, as well as the estimates and liabilities branch, in which the navy estimates are largely prepared after having been proposed and worked out in the executive departments of the Admiralty. There are also ships' establishments and salaries branches. The navy pay division includes the full and half-pay branch and a registry section. There is also the seamen's pay branch, which audits ships' ledgers and wages, and has charge of all matters concerning the wages of seamen. The victualling audit is also in this branch, and is concerned with payments for savings in lieu of victualling and some other matters. Further, the navy pay division examines ships' ledgers, and is concerned with the service, characters, ages, &c., of men as well as with allotments and pensions. The third division of the accountant-general's department, known as that of invoices and claims, conducts a vast amount of clerical work through many branches, and is concerned with the management of Naval Savings Banks and matters touching prize-money and bounties.

The importance of this great department of the Admiralty cannot be overrated. It is, in the first place, of supreme importance that the navy estimates should be placed upon a sound financial basis; and in practice the board requires the concurrence of the accountant-general to the votes before they are approved, and thus in greater or less degree this officer is concerned in the preparation of every one of the votes. He does not concern himself with matters of larger policy outside the domain of finance, and it must be confessed that there appears to be something anomalous in his "review" of naval expenditure. It is, however, a mark of the flexibility or elasticity of the Admiralty system that in practice the operations of the accountant-general's department work easily, and that Admiralty finance is recognized as having been placed upon a sound and efficient basis. There are important financial officers outside the accountant-gen-

eral's department concerned with assisting the Controller. The inspector of dockyard expense accounts, who is entirely in the Controller's department, enables him to exercise careful supervision over expenditure and the distribution of funds to special purposes. This work, however, though highly important, is merely one part of the system of financial control. Within recent years the bonds have been considerably tightened, and the work is untainted by corruption. It is true that in exercising rigid supervision over expenditure the work has become more centralized than is desirable, and it is a mark of change within recent years that local officers have been in larger measure deprived of independent powers. This, indeed, is a necessary condition of financial control, or at least a condition which it is not easy to change where rigid control is necessary. (R. V. H.; J. LD.)

UNITED STATES.

The President of the United States is commander-in-chief of the navy—a constitutional prerogative which he seldom asserts. The Navy Department is administered by a civilian Secretary of the Navy—a cabinet officer appointed by the President—who exercises general supervision. Next in authority is the Assistant-Secretary, also a civilian nominee, who acts as an assistant, and has, besides, certain specific duties, including general supervision of the marine corps, naval militia, and naval stations beyond the continental limits of the United States. The details of administration are supervised by the chiefs of bureaus, of which there are eight. They are appointed by the President from the navy list for a period of four years, and have the rank of rear-admiral while serving in this capacity. They have direct control of the business and correspondence pertaining to their respective bureaus; and orders emanating from them have the same force as though issued by the Secretary.

The bureau of *Navigation* is the executive, or military, bureau, and as such promulgates and enforces the orders and regulations prescribed by the Secretary; it has general direction of the procurement, education, assignment, and discipline of the *personnel*. It also controls the movements of ships, including the authorization of manoeuvres and drills, such as target practice. The bureau of *Equipment* has charge of all electrical appliances, compasses, charts, and fuel, and generally all that relates to the equipment of vessels, exclusive of those articles that come naturally under the cognizance of other bureaus. It has charge of the naval observatory, where the ephemeris is prepared annually, and of the hydrographic office, where charts, sailing directions, notices to mariners, &c., are issued. The bureau of *Ordnance* has charge of the gun factory, proving ground, and torpedo station, and all naval magazines; all the details that pertain to the manufacture, tests, installation, or storage of all offensive and defensive apparatus, including armour, ammunition hoists, ammunition rooms, &c., though much of the actual installation is performed by the bureau of construction after consultation with the bureau of ordnance. The bureau of *Construction and repair* has charge of the designing, building, and repairing of hulls of ships, including turrets, spars, and many other accessories. It builds all boats, has charge of the docking of vessels and the care of ships in reserve. The chief of this bureau is usually a naval constructor. The bureau of *Steam engineering* has charge of all that relates to the designing, building, and repairing of steam machinery, and with all the steam connexions on board ship. The bureau of *Supplies and accounts* procures and distributes provisions, clothing, and

supplies of the pay department afloat, and acts as the purchasing agent for all materials used at naval stations, except for the medical department and marine corps. It also has charge of the disbursement of money and keeping of accounts. The chief of this bureau is a pay officer. The bureau of *Medicine and surgery* has charge of all naval hospitals, dispensaries, and laboratories, and of all that pertains to the care of sick afloat and ashore. The chief of this bureau is a medical officer. The bureau of *Yards and docks* has charge of construction and maintenance of wet and dry docks, buildings, railways, cranes, and generally all permanent constructions at naval stations. The chief of this bureau is often a civil engineer.

Under the cognizance of the Secretary's office is the office of the judge-advocate-general, an officer selected by the President from the navy list for a term of four years, with the rank of captain while so serving. He is legal adviser to the Department, and reviews the records of all courts and statutory boards. Under the cognizance of the Assistant-Secretary's office is the office of naval intelligence, which collates information on naval matters obtainable at home and abroad. The staff is composed of naval officers on shore duty, the senior in charge being usually a captain, and known as chief intelligence officer. Several boards are employed under the various bureaus, or directly as advisers to the Secretary. Some are permanent in character, while others are composed of officers employed on other duty, and are convoked periodically or when required. The naval policy board is composed of officers of high rank, and meets once a month; its duties conform to those of the general staff in armies. The board on construction consists of the chiefs of bureaus of Ordnance, Equipment, Construction and repair, Steam engineering, and the chief intelligence officer. Its duty is to advise the Secretary in all matters relating to the construction policy in detail. The general construction policy is suggested by the naval policy board. The board of inspection and survey is composed of representatives of all bureaus, who inspect vessels soon after commission and on return from a cruise, and report on the condition of the ship and efficiency of its *personnel*; it also conducts the official trials of new vessels. The boards for the examination of officers for promotion are composed of officers of the corps to which the candidate belongs and of medical officers. Every officer is examined professionally, morally, and physically at each promotion. The Navy Department is located at Washington, D.C., and occupies a building together with the State and War Departments (the latter being charged solely with army affairs).

The *personnel* is limited in number by law. The allowance of commissioned officers in July 1900 was 1449, distributed as shown in the table. All *Personnel* others than line officers are termed, in contradistinction from them, staff officers. The relative navy or army rank of any staff grade may be ascertained from the table on p. 79.

The engineer corps was abolished in 1899, the then engineer-officers becoming line officers in their respective relative grades. Line officers are the military and executive branch, and are required besides to perform engineer duties. They are graduates of the Naval Academy. Vacancies occurring in the construction corps are filled from the graduates of the Naval Academy having the highest standing in scholarship, who are given a two years' graduate course, generally abroad, on being graduated from the Academy, and are then appointed assistant naval constructors. All other staff officers are appointed directly from civil life by the President, from candidates passing prescribed examinations. Each repre-

sentative and delegate in Congress has authority to nominate a candidate for naval cadet whenever his congressional district has no representative in the Naval Academy. The candidate must be a resident of the district which the Congressman represents, between fifteen and twenty years old, and must pass prescribed mental and physical examinations. The President is allowed ten representatives at the Academy at all times, appointed

⁴ Naval constructors with rank of lieut.-commander or lieutenant. Assistant naval constructors have rank of lieutenant, or lieutenant (junior grade).

"at large," and one appointed from the District of Columbia.

The course of instruction at the Academy is four years, each comprising eight months' study, three months' practice cruise, and one month's furlough. At the expiration of four years, cadets are sent to cruising ships for two years' further instruction, and are then commissioned ensigns. After three years' further sea service, ensigns are promoted to lieutenants (junior grade). After this, promotion is dependent upon seniority alone, the senior officer in any grade being promoted to the lowest number in the next higher grade when a vacancy occurs in the higher grade, and not before. All officers are retired on three-fourths sea pay at the age of sixty-two, or whenever a board of medical officers certifies that an officer is not physically qualified to perform all duties of his grade. A few officers are allowed to retire voluntarily in certain circumstances, to stimulate promotion. Any officer on the retired list may be ordered by the Secretary to such duty as he may be able to perform: this is a legal provision to provide for emergencies. Promotion in the staff corps is dependent upon seniority, though relative rank in the lower grades in some corps somewhat depends upon promotion of line officers of the same length of service, and accounts for the existence of staff officers in the same grade having different ranks. All sea-going officers, after commission, are required to spend three years at sea, and are then usually employed on shore-duty for a time, according to the needs of the service—short terms of shore-duty thereafter alternating with three-year cruises. This rule is adhered to as strictly as circumstances will permit. Shore-duty includes executive or distinctly professional duties in the Navy Department, under its bureaus, and at navy yards and stations; inspection of ordnance, machinery, dynamos, &c., under construction by private firms; duty on numerous temporary or permanent boards; instructors at the Naval Academy; recruiting duty; charge of branch hydrographic offices; inspection duty in the lighthouse establishment; at state nautical schools; as attachés with United States legations; and many others. Naval constructors (usually), civil engineers, and professors of mathematics are continuously employed on shore-duty connected with their professions, the Naval Observatory, Nautical Almanac, and the Naval Academy employing most of the last.

Warrant officers include boatswains, gunners, carpenters, sailmakers, warrant machinists, and pharmacists. The last are limited in number to twenty-five, and are

stationed at hospitals, &c., ashore. Warrant machinists are at present limited by law to 150. The number of the others is at the discretion of the Secretary. The number in January 1901 was as follows: boatswains, 91; gunners, 95; carpenters, 62; sailmakers 10. They are appointed by the Secretary, preference being given to enlisted men in the navy who have shown marked ability for the positions. They must be between twenty-one and thirty-five years of age, and pass an examination. After serving satisfactorily for one year under an acting appointment, they receive warrants that secure the permanency of their office. Ten years after appointment, boatswains, gunners, carpenters, and sailmakers are eligible for examination for a commission as chief-boatswain, &c., and as such they rank with, but next after, ensigns. Mates are rated by the Secretary from seamen or ordinary seamen. They have no relative rank, but take precedence of all petty officers. Their duties approximate to those of boatswains, though they seldom serve on large cruising vessels. There were but eight on the active list in January 1901. Clerks to pay officers are appointed by the Secretary on the nominations of the pay officers. They have no rank and are not promoted or retired. Their appointments are revoked when their services are no longer needed.

The enlisted force numbers 20,000, including 2500 apprentices. Boys between fifteen and seventeen years old of good character, who can read and write and pass the physical examination, may enlist for the term of their minority. They enlist as third class apprentices, and are given six months' instruction at a training station, and thence go to sea in apprentice training vessels. When proficient they are transferred to regular cruising vessels as second class, and when further qualified are rated first class. All other enlistments are for four years. First enlistments are made only in the following ratings and between the ages specified:—

Rating.	Years of Age.
Seamen	21 to 35
Ordinary seamen	18 " 30
Landsmen	18 " 25
Shipwrights	21 " 35
Blacksmiths	21 " 35
Plumbers and fitters	21 " 35
Sailmakers' mates	21 " 35
Machinists, first class	21 " 35
Machinists, second class	21 " 35
Electricians, third class	21 " 35
Boilermakers	21 " 35

Rating.	Years of Age.
Coppersmiths	21 to 35
Firemen, first class	21 " 35
Firemen, second class	21 " 35
Coal-passers	21 " 35
Hospital stewards	21 " 30
Hospital apprentices, first class	21 " 28
" apprentices	18 " 25
Officers' stewards	21 " 35
Officers' cooks	21 " 35
Mess attendants	18 " 30
Ship's cooks, fourth class	18 " 30
Musicians, first class	21 " 35
Musicians, second class	21 " 35
Buglers	21 " 35
Painters	21 " 35

Recruits must speak English. Landsmen are usually sent to sea on special training-ships until proficient, and are then sent into general service. Raw recruits may enlist as landsmen, or coal-passers, or mess attendants. Ordinary seamen must have served two years, and seamen four years before the mast, prior to first enlistment as such; and before enlistment in any other rating allowed on first enlistment, applicants must prove their ability to hold such rating. Landsmen, coal-passers, &c., as soon as they become proficient, are advanced to higher grades and, if American citizens, may eventually become petty officers (ranking with army non-commissioned officers), with acting appointments. In twelve months, or as soon thereafter as proficiency is established, the acting appointment is made permanent, and an acting appointment for the next higher grade is issued, &c. Permanent appointments are not revokable except by sentence of court-martial, and a man re-enlists in that rating for which he held a permanent appointment in his previous enlistment. All persons re-enlisting within four months after expiration of previous enlistment are entitled to a bounty equal to four months' pay, and in addition receive a "continuous service certificate," which entitles them to higher pay and to other special considerations. The same is true for each re-enlistment. When an enlisted man completes thirty years' service and is over fifty years of age he may retire on three-fourths pay.

The marine corps constitutes a wholly separate military body, though under the control of the Navy Department. It is organized, equipped, uniformed, instructed, and drilled similarly to the army, both as infantrymen and artillerymen, and hence may be employed as soldiers either afloat or ashore. The corps is commanded by a brigadier-general, with headquarters in Washington, who bears to the Secretary a relation similar to that of a chief of bureau. The general has a general staff of ten members, and the remaining officers allowed by law are as follows: 5 colonels, 5 lieutenant-colonels, 10 majors, 60 captains, 60 first lieutenants, and 60 second lieutenants. Although the organization closely follows the army system, regimental or even permanent battalion organizations are impracticable, owing to their numerous and widely-separated stations. Practically all shore stations have barracks where marines are enlisted and drilled. At these places they also do sentry, police, and orderly duties. From such stations they are sent to ships for sea duty. Nearly all ships carry a body of marines known as the guard, varying in size from a few men commanded by a sergeant, on small ships, to eighty or more, with one or more commissioned officers, on large vessels. It is customary to cause all marines to serve at sea three of the four years of each enlistment. On board ship they perform sentry and orderly duty, and assist in police duties. They are also instructed in many exercises pertaining to the navy, as rowing, naval signalling, gun drill, &c. In action they act as riflemen, and on

many ships serve a portion of the guns. When circumstances require a force to be landed from ships present to guard American interests in foreign countries, legations, &c., the marine guard is usually sent, though, if numerically insufficient, sailors are landed also. Large bodies of marines are sometimes sent in transports for this purpose from other stations. Marines also garrison places beyond the territorial limits of the United States which are under navy control. The enlisted force numbers 6000. Candidates for first enlistment must be between the ages of 21 and 35 and unmarried, must be citizens of the United States, be able to read, write, and speak English, and pass a physical examination. Second lieutenants are appointed from civil life after examination or from the graduates of the Naval Academy. Promotion is by seniority as in the navy. Occasional opportunities are also given meritorious enlisted men to secure commissions.

NAVY AND MARINE CORPS PAY TABLES.

TABLE I.—Active List: Officers of the Line, Medical and Pay Corps of the Navy, and Officers of the Marine Corps.

Rank.	On Sea Duty or Shore Duty beyond Sea.	On Shore.
Admiral	\$ 13,500	\$ 13,500
Rear-admirals—		
First nine	7,500	6,375
Second nine	5,500	4,675
Chiefs of bureaus and brigadier-general commandant of marine corps	5,500
Captains, navy	3,500	2,975
Judge-advocate-general and colonels, marine corps, line and staff	3,500	3,500
Commanders, navy	3,000	2,550
Lieutenant-colonels, marine corps, line and staff	3,000	3,000
Lieutenant-commanders, navy	2,500	2,125
Majors, marine corps, line and staff	2,500	2,500
Lieutenants, navy	1,800	1,530
Captains, marine corps —		
Line	1,800	1,800
Staff	2,000	2,000
Lieutenants (junior grade), navy	1,500	1,275
First lieutenants and leader of band, marine corps	1,500	1,500
Ensigns, navy	1,400	1,190
Second lieutenants, marine corps, chief boatswains, chief gunners, chief carpenters, and chief sailmakers	1,400	1,400

Remarks.

All officers paid under this table below the rank of rear-admiral or brigadier-general are entitled by law to 10 per cent. upon the full yearly pay of their grades for each and every period of five years' service, as increase for length of service, or "longevity pay," computed upon their total actual service in army, navy, and marine corps; provided that the total amount of such increase shall not exceed 40 per cent. upon the full yearly pay of the grade; and provided further that the pay of a captain in the navy or colonel of marines shall not exceed \$4500 per annum, and that of a commander in the navy or lieutenant-colonel of marines \$4000 per annum.

ALLOWANCES.—The monthly commutation for quarters of the admiral is \$125. All other commissioned officers of the line and of the medical and pay corps of the navy, and all officers of the marine corps, are entitled to public quarters while on shore-duty or commutation therefor, the amount varying between \$24 per month for an ensign and \$72 for a rear-admiral. Officers serving ashore in Cuba, Porto Rico, the Philippine Islands, Hawaii, or Alaska are allowed 10 per cent. increase of the pay proper.

TABLE II.—Active List: Other Officers of the Navy and others who are paid as Officers.

The incessant changes in *matériel* and its distribution render a comprehensive description of this subject of little more than ephemeral value. On 1st January *Matériel.* 1901 there were 239 vessels of all classes on the navy list, and 67 more under construction.

TABLE A. Completed Vessels—Modern Construction.

7 1st class battleships	10,288 to 11,565 tons.
1 2nd „ battleship	6,315 „
2 armoured cruisers	8,200 to 9,215 „
5 protected „	3,000 to 7,375 „
3 unprotected „	2,089 „
19 gunboats	839 to 1,710 „
6 monitors	3,990 to 6,060 „
1 harbour-defence ram	2,155 „
1 dynamite cruiser	929 „
20 torpedo boats	46 to 273 „
1 „ boat (submarine)	73 „

76

All of the above are of modern steel construction (except the monitors, which are of iron), the first commission of the oldest dating December 1885, and the great majority were first commissioned since 1890, and most built prior to 1890 have since been rebuilt. Next in order of practical efficiency are the converted vessels purchased prior to or during the Spanish war. Many

are now in commission and may be retained in service indefinitely.

TABLE B. Auxiliary Fighting Ships.

5 converted cruisers	4260 to 6888 tons.
4 „ yachts	806 to 2690 „
11 „ „	302 to 786 „
8 „ „	82 to 192 „
26 „ tugs	150 to 840 „
—	
54	

There are also 26 gunboats captured or purchased from Spain, varying in size from 42 to 1159 tons, and in characteristics from single-screw iron boats to twin-screw steel craft of late design and high efficiency.

TABLE C. Auxiliaries.

16 colliers	3085 to 7500 tons.
2 distilling ships	6100 to 6206 „
1 tank „	6200 „
1 hospital „	4700 „
5 supply „	2600 to 7000 „
1 marine transport	1400 „
15 unarmed tugs	192 to 450 „
—	
41	

The following vessels of old construction are still seaworthy and efficient for their type, and many are in commission—

TABLE D. *Old Construction.*

8	single-turret iron monitors.
2	iron steam cruisers.
2	„ paddle gunboats.
7	wooden steam cruisers.
1	„ torpedo boat of 17 knots speed.
20	

TABLE E. *Inefficient.*

22 wooden sailing vessels, mostly unserviceable, except as receiving ships, &c.

TABLE F. *Under Construction.*

10	1st class battleships . . .	11,525 to 15,000	tons.
6	armoured cruisers . . .	13,600 to 14,000	„
3	protected „ . . .	9,600	„
6	„ „ . . .	3,100	„
4	monitors . . .	3,214	„
1	gunboat		
6	submarine boats . . .	120	„
1	torpedo craft . . .	165 to 420	„

67

United States naval vessels are, as a rule, built at private yards under contracts awarded after competition. The Government is not committed to any fixed policy or building programme. Each year the Secretary recom-

mends certain new construction. The final action rests with Congress, which must appropriate money for the new ships before the construction can be commenced. Repairing and reconstruction are usually done at Government navy yards.

Ships in commission are distributed among five stations: (1) the North Atlantic, which includes the Atlantic coast of the United States, Central America, and South America as far as the Amazon, also the West Indies; (2) the South Atlantic, which includes the remainder of the Atlantic coast of South America and both coasts of South Africa; (3) the European, which comprises the coast of Europe, including the inland seas, and the North Atlantic coast of Africa; (4) the Asiatic station, comprising the coast of Asia, including the islands north of the equator, also the east coast of North Africa; (5) the Pacific station, comprising the Pacific coast of North and South America, and Australia and the adjacent islands lying south of the equator. Each station is commanded by a flag officer, and the number of ships under the command varies according to circumstances. Ships in commission on special service, such as training, gunnery, surveying ships, &c., are not attached to stations. The shore stations of the navy are enumerated in the article on DOCKYARDS. (W. T. S.)

Admiralty, Cinque Ports Court of.—The Court of Admiralty for the Cinque Ports exercises a coordinate but not exclusive Admiralty jurisdiction over persons and things found within the territory of the Cinque Ports. The limits of its jurisdiction were declared at an inquisition taken at the Court of Admiralty, held by the seaside at Dover in 1682, to extend from Shore Beacon in Essex to Redcliff, near Seaford, in Sussex; and with regard to salvage, they comprise all the sea between Seaford in Sussex to a point five miles off Cape Grisnez on the coast of France, and the coast of Essex. An older inquisition of 1526 is given by Mr Marsden in his *Select Pleas of the Court of Admiralty*, II. xxx. The court is an ancient one. The judge sits as the official and commissary of the Lord Warden, just as the judge of the High Court of Admiralty sat as the official and commissary of the Lord High Admiral. And, as the office of Lord Warden is more ancient than the office of Lord High Admiral (*The Lord Warden v. King in his office of Admiralty*, 1831, 2 Hagg. Admy. Rep. 438), it is probable that the Cinque Ports Court is the more ancient of the two.

The jurisdiction of the court has been, except in one matter of mere antiquarian curiosity, unaffected by statute. It exercises only, therefore, such jurisdiction as the High Court of Admiralty exercised, apart from the restraining statutes, 13 Ric. II. c. 5, 15 Ric. II. c. 3, and the enabling statutes, 3 and 4 Vict. c. 65, and 24 Vict. c. 10. Cases of collision have been tried in it (the "Vivid," 1 *Asp. Maritime Law Cases*, 601). But salvage cases (the "Clarisse," *Swabey*, 129; the "Marie," *Law. Rep.* 7 *P.D.* 203) are the principal cases now tried. It has no prize jurisdiction. The one case in which jurisdiction has been given to it by statute is to enforce forfeitures under 5 Eliz. c. 5.

Mr Arthur Cohen, K.C., is the present judge. His predecessor was Dr (afterwards the Right Hon. Sir Robert Joseph) Phillimore, who succeeded his father in the same office, and was judge from 1855 to 1875. As Sir Robert Phillimore was also the last judge of the High Court of Admiralty, from 1867 (the date of his appointment to the High Court) to 1875, the two offices were probably for the first time in history held by the same

person. The appointment is by the Lord Warden. Dr Phillimore's patent had a grant of the "place or office of judge official and commissary of the Court of Admiralty of the Cinque Ports, and their members and appurtenances, and to be assistant to my lieutenant of Dover castle in all such affairs and business concerning the said Court of Admiralty wherein yourself and assistance shall be requisite and necessary." Of old the court sat sometimes at Sandwich, sometimes at other ports. But the regular place for the sitting of the court has for a long time been, and still is, the aisle of St James's Church, Dover. For convenience the judge often sits at the Royal Courts of Justice. The office of marshal in the High Court is represented in this court by a serjeant, who also bears a silver oar. There is a registrar, as in the High Court. The appeal is to the queen in council, and is heard by the judicial committee. The court can hear appeals from the Cinque Ports salvage commissioners, such appeals being final (1 and 2 Geo. IV. c. 76, § 4). Actions may be transferred to it, and appeals made to it, from the county courts in all cases arising within the jurisdiction of the Cinque Ports as defined by that Act. At the solemn installation of the Lord Warden the judge as the next principal officer installs him.

The Cinque Ports from the earliest times claimed to be exempt from the jurisdiction of the admiral of England. Their early charters do not, like those of Bristol and other seaports, express this exemption in terms. It seems to have been derived from the general words of the charters which preserve their liberties and privileges.

The Lord Warden's claim to prize was raised in, but not finally decided by, the High Court of Admiralty in the "Ooster Ems," 1 *C. Rob.* 284, 1783.

See *Boys. Sandwich and Cinque Ports.*—KNOCKER. *Grand Court of Shepway*, 1862. (W. G. F. P.)

Admiralty, High Court of.—The High Court of Admiralty was the court of the deputy or lieutenant of the admiral. It is supposed in the *Black Book of the Admiralty* to have been founded in the reign of Edward I.; but it would appear, from the learned discussion of Mr Marsden, that it was established as a civil

court by Edward III. in the year 1360; the power of the admiral to determine matters of discipline in the fleet, and possibly questions of piracy and prize, being somewhat earlier. Even then the court as such took no formal shape; but the various admirals began to receive in their patents express grants of jurisdiction with powers to appoint lieutenants or deputies. At first there were separate admirals or rear-admirals of the north, south, and west, each with deputies and courts. A list of them was collected by Sir H. Spelman. These were merged in or absorbed by one high court early in the 15th century. Sir Thomas Beaufort, afterwards earl of Dorset and duke of Exeter (appointed admiral of the fleet, 9 Henry IV., and admiral of England, Ireland, and Aquitaine 1412, which latter office he held till his death in 1417), certainly had a court, with a marshal and other officers, and forms of legal process—mandates, warrants, citations, compulsories, proxies, &c. For the subject matters of the ancient Admiralty jurisdiction it is usual to refer to the inquisition of Queenborough, in 1375. Complaints of encroachment of jurisdiction by the Admiralty courts led to the restraining Acts, 13 Ric. II. c. 5, 15 Ric. II. c. 3, and 2 Hen. IV. c. 11.

The original object of the institution of the courts or court seems to have been to prevent or punish piracy and other crimes upon the narrow seas and to deal with questions of prize; but civil jurisdiction soon followed.

Jurisdiction.

The jurisdiction in criminal matters was transferred by 28 Hen. VIII. c. 15 to the admiral or his deputy and three or four other substantial persons appointed by the Lord Chancellor, who were to proceed according to the course of the common law. By 4 and 5 Will. IV. c. 36, cognizance of crimes committed within the jurisdiction of the Admiralty was given to the central criminal court. By 7 and 8 Vict. c. 2, it has been also given to the justices of assize; and crimes done within the jurisdiction of the Admiralty are now tried as crimes committed within the body of a county. See also the Criminal Law Consolidation Acts of 24 and 25 Victoria.

From the time of Henry IV. the only legislation affecting the civil jurisdiction of the High Court of Admiralty till the time of Queen Victoria is to be found in § 10 of 32 Hen. VIII. c. 14, enabling the admiral or his lieutenant to decide on certain complaints of freighters against shipmasters for delay in sailing, and § 34 of 5 Eliz. c. 5, giving the Lord High Admiral of England, the Lord Warden of the Cinque Ports, their lieutenants and judges, co-ordinate power with other judges to enforce forfeitures under that Act—a very curious and miscellaneous statute called "An Act for the Maintenance of the Navy."

In the Act 25 Hen. VIII. c. 19, with regard to ecclesiastical appeals from the courts of the archbishops to the Crown, it is provided that the appeal shall be to the king in Chancery, "and that upon every such appeal a commission shall be directed under the great seal to such persons as shall be named by the king's highness, his heirs or successors, like as in cases of appeal from the Admiralty Court." The appeal to these "persons," called delegates, continued until it was transferred first to the Privy Council, and then to the judicial committee of the Privy Council by the statutes 2 and 3 Will. IV. c. 92, and 3 and 4 Will. IV. c. 41.

The early jurisdiction of the court appears to have been exercised very much under the same procedure as that used by the Courts of Common Law. Juries are mentioned, sometimes of the county and sometimes of the county and merchants. But the connexion with foreign parts led to the gradual introduction of a procedure resembling that coming into use on the Continent and based on the Roman civil law. The statute 28 Hen. VIII. c. 15, states the

objection to this application of the civil law to the trial of criminal cases with much force: "After the course of the civil laws, the nature whereof is that before any judgment of death can be given against the offenders, either they must plainly confess their offences (which they will never do without torture or pain), or else their offences be so plainly and directly proved by witness indifferent such as saw their offences committed, which cannot be gotten but by chance at few times."

The material enactments of the restraining statutes were as follows:—13 Ric. II. c. 5 provided that "the admirals and their deputies shall not meddle from henceforth of anything done within the **Restraining Acts.** realm, but only of a thing done upon the sea, as it hath been used in the time of the noble prince king Edward, grandfather of our lord the king that now is." 15 Ric. II. c. 3 provided, that "of all manner of contracts, pleas, and quarrels, and other things rising within the bodies of the counties as well by land as by water, and also of wreck of the sea, the admiral's court shall have no manner of cognizance, power, nor jurisdiction; but all such manner of contracts, pleas, and quarrels, and all other things rising within the bodies of counties, as well by land as by water, as afore, and also wreck of the sea, shall be tried, determined, discussed, and remedied by the laws of the land, and not before nor by the admiral, nor his lieutenant in any wise. Nevertheless, of the death of a man, and of a maihem done in great ships, being and hovering in the main stream of great rivers, only beneath the [bridges] of the same rivers [nigh] to the sea, and in none other places of the same rivers, the admiral shall have cognizance, and also to arrest ships in the great flotes for the great voyages of the king and of the realm; saving always to the king all manner of forfeitures and profits thereof coming; and he shall have also jurisdiction upon the said flotes, during the said voyages only; saving always to the lords, cities, and boroughs, their liberties and franchises." 2 Hen. IV. c. 11 adds nothing by way of definition or restriction, but merely gives additional remedies against encroachments, providing heavy fines for those who improperly sue in the court, and those officials of the court who improperly assert jurisdiction. It was repealed by 24 Vict. c. 10. The statutes of Richard, except the enabling part of the second, were repealed by 42 and 43 Vict. c. 59. The formation of a High Court of Justice rendered them obsolete.

In the reign of James I. the chronic controversies between the Courts of Common Law and the Admiralty Court as to the limits of their respective jurisdictions reached an acute stage. We find the records of it in the second volume of Mr Marsden's *Select Pleas in the Court of Admiralty*, and in Lord Coke's writings: *Reports*, part xiii. 51; *Institutes*, part iv. chap. 22. In this latter passage Lord Coke records how, notwithstanding an agreement asserted to have been made in 1575 between the justices of the King's Bench and the judge of the Admiralty, the judges of the Common Law Courts successfully maintained their right to prohibit suits in Admiralty upon contracts made on shore, or within havens, or creeks, or tidal rivers, if the waters were within the body of any county, wheresoever such contracts were broken, for torts committed within the body of a county, whether on land or water, and for contracts made in parts beyond the seas. It is due to the memory of the judges of Lord Coke's time to say that, at any rate as regards contracts made *in partibus transmarinis*, the same rule appears to have been applied at least as early as 36 Hen. VIII., the judges then holding that "for actions transitory abroad action may lie at common law."

All the while, however, the patents of the Admiralty

judge purported to confer on him a far ampler jurisdiction than the jealousy of the other courts would concede to him. The patent of the last judge of the court, Sir Robert Joseph Phillimore, dated 23rd August 1867, styles him "Lieut. Offl. Princ. and Commissary Genl. and Special in our High Court of Admiralty of Eng. and President and Judge of the same," and gives him power to take cognizance of "all causes, civil and maritime, also all contracts, complaints, offences or suspected offences, crimes, pleas, debts, exchanges, accounts, policies of assurance, loading of ships, and all other matters and contracts which relate to freight due for the use of ships, transportation, money, or bottomry; also all suits civil and maritime between merchants or between proprietors of ships and other vessels for matters in, upon, or by the sea, or public streams, of fresh-water ports, rivers, nooks, and places overflowed whatsoever within the ebbing and flowing of the sea and high-water mark, or upon any of the shores or banks adjacent from any of the first bridges towards the sea through England and Ireland and the dominions thereof, or elsewhere beyond the seas." Power is also given to hear appeals from vice-admirals; also "to arrest . . . according to the civil laws and ancient customs of our high court . . . all ships, persons, things, goods, wares, and merchandise"; also "to enquire by the oaths of honest and lawful men . . . of all . . . things which . . . ought to be enquired after, and to mulct, arrest, punish, chastise, and reform"; also "to preserve the public streams of our Admiralty as well for the preservation of our royal navy, and of the fleets and vessels of our kingdom . . . as of whatsoever fishes increasing in the rivers"; also "to reform nets too straight and other unlawful engines and instruments whatsoever for the catching of fishes"; also to take cognizance "of the wreck of the sea . . . and of the death, drowning, and view of dead bodies," and the conservation of the statutes concerning wreck of the sea and the office of coroner [3 and 4 Edw. I.], and concerning pillages [27 Edw. III.], and "the cognizance of mayhem" within the ebb and flow of the tide; all in as ample manner and form as they were enjoyed by Dr David Lewis [judge from 1558-84], Sir Julius Cæsar, and the other judges in order (22 in all) before Sir Robert Phillimore. This form of patent differs in but few respects from the earlier Latin patents—*tempore* Henry VIII.—except that they have a clause *non obstantibus statutis*.

As has been said, however, the contention of the Common Law judges prevailed, and the Admiralty Court (except during a temporary revival under Cromwell) sank into comparative insignificance during the 17th century. The great maritime wars of the 18th century gave scope to the exercise of its prize jurisdiction; and its international importance as a prize court in the latter half of the 18th and the first part of the 19th centuries is a matter of common historical knowledge.

There were other great judges; but Sir William Scott, afterwards Lord Stowell, is the most famous. Before his time there were no reports of admiralty cases, except Hay and Marriott's prize decisions. But from his time onwards there has been a continuous stream of Admiralty Reports, and we begin to find important cases decided on the instance as well as on the prize side.

In the reign of Queen Victoria, two enabling statutes, 3 and 4 Vict. c. 65 and 24 Vict. c. 10, were passed and greatly enlarged the jurisdiction of the court. The manner in which these statutes were administered by Dr Lushington and Sir R. Phillimore, whose tenure of office covered the whole period of the Queen's reign till the creation of the High Court of Justice, the valuable assistance

rendered by the nautical assessors from the Trinity House, the great increase of shipping, especially of steam shipping, and the number and gravity of cases of collision, salvage, and damage to cargo, restored the activity of the court and made it one of the most important tribunals of the country. In 1875, by the operation of the Judicature Acts of 1873 and 1875, the High Court of Admiralty was with the other great courts of England formed into the High Court of Justice. The principal officers of the court in subordination to the judge were the registrar (an office which always points to a connexion with canon or civil law), and the marshal, who acted as the maritime sheriff, having for his baton of office a silver oar. The assistance of the Trinity Masters, which has been already mentioned, was provided for in the charter of incorporation of the Trinity House. These officers and their assistance have been preserved in the High Court of Justice.

See SIR TRAVERS TWISS. *Black Book of the Admiralty*. Rolls series.—MARDEN. *Select Pleas in the Court of Admiralty*, published by the Selden Society.—GODOLPHIN. *View of the Admiral Jurisdiction*. (W. G. F. P.)

Admiralty Jurisdiction.—The courts by which, as far as we know, Admiralty jurisdiction in civil matters was first exercised were the following. In and throughout England the courts of the several admirals soon combined into one High Court of Admiralty. Within the territories of the Cinque Ports the Court of Admiralty of the Cinque Ports exercised a co-ordinate jurisdiction. In certain towns and places there were local courts of Vice-Admiralty. In Scotland there existed the Scottish High Court of Admiralty, in Ireland the Irish High Court of Admiralty. Of these courts that of the Cinque Ports alone remains untouched. The Scottish court was absorbed, and its jurisdiction given to the Court of Session by 11 Geo. IV. and 1 Will. IV. c. 69—not, however, till a decision given by it and the appeal therefrom to the House of Lords had established a remarkable rule of Admiralty law in cases of collision (*Hay v. Le Neve*, 1824, 2 Shaw, *Sc. App. Cas.* 395). The local Vice-Admiralty Courts in England had ceased to do much work when they were abolished by the Municipal Corporations Act, 1835; the High Court became, with the other superior courts, a component part of the High Court of Justice by virtue of the Judicature Acts, 1873 and 1875. And the Irish court has in like manner become a part of the High Court of Justice in Ireland by the Judicature Act for that country.

As England first, and Great Britain afterwards, acquired colonies and possessions beyond seas, Vice-Admiralty Courts were established. The earliest known was that in Jamaica, established in the year 1662. Some Vice-Admiralty Courts which were created for prize purposes in the last century were suffered to expire after 1815. In the year 1863, when the act regulating the Vice-Admiralty Courts was passed, there were Vice-Admiralty Courts at Antigua, Bahamas, Barbadoes, Bermuda, British Columbia, British Guiana, British Honduras, Cape of Good Hope, Ceylon, Dominica, Falkland Islands, Gambia River, Gibraltar, Gold Coast, Grenada, Hong Kong, Jamaica, Labuan, Lagos, Lower Canada (otherwise Quebec), Malta, Mauritius, Montserrat, Natal, Nevis, New Brunswick, Newfoundland, New South Wales, New Zealand, Nova Scotia (otherwise Halifax), Prince Edward Island, Queensland, Saint Christopher, Saint Helena, Saint Lucia, Saint Vincent, Sierra Leone, South Australia, Tasmania, Tobago, Trinidad, Vancouver's Island, Victoria, Virgin Islands (otherwise Tortola), Western Australia. By the Act of 1867 one for the Straits Settlements was added. These courts have been regulated from time to time by the following statutes:

Moderna progress.

Vice-Admiralty Courts.

2 Will. IV. c. 51, 26 Vict. c. 24 already cited, and 30 and 31 Vict. c. 45. In 1890 the Colonial Courts of Admiralty Act provided that, except in the colonies of New South Wales, Victoria, Saint Helena, and British Honduras, Vice-Admiralty Courts should be abolished, and a substitution made of Colonial Courts of Admiralty. There is power, however, reserved to the Crown to erect through the Admiralty in any British possession any Vice-Admiralty Court, except in India or any British possession having a representative legislature. No Vice-Admiralty Court so established can exercise any jurisdiction except for some purpose relating to prize, the royal navy, the slave trade, foreign enlistment, Pacific Islanders' protection, and questions relating to treaties or conventions on international law. Vice-Admiralty Courts exercised all usual Admiralty jurisdiction, and in addition a certain revenue jurisdiction, and jurisdiction over matters of slave trade and prize (royal navy) and under the Pacific Islanders' Protection Act. The appeal from Vice-Admiralty Courts used to lie to the High Court of Admiralty of England, but has been transferred to the King in Council.

Modern statutes have given Admiralty jurisdiction to the county courts in the following matters:—Salvage, where the value of the salvaged property does not exceed £1000, or the claim for reward £300; towage, necessities, and wages, where the claim does not exceed £150; claims for damage to cargo, or by collision, up to £300 (and for sums above these prescribed limits by agreement between the parties); and claims arising out of breaches of charter parties and other contracts for carriages of goods in foreign ships, or torts in respect thereof up to £300. This jurisdiction is restricted to subjects over which jurisdiction was possessed by the High Court of Admiralty at the time when the first of these Acts was passed, except as regards the last branch of it (The "Aline," 1880, 5 Ex. Div. 227; *Reg. v. Judge of City of London Court*, 1892, 1 Q.B. 272). In analogy with the county court Admiralty jurisdiction created in England, a limited Admiralty jurisdiction has been given in Ireland to the recorders of certain boroughs and the chairmen of certain Quarter Sessions; and in salvage cases, where a county court in England would have jurisdiction, magistrates, recorders, and chairmen of Quarter Sessions may have jurisdiction as official arbitrators (57 and 58 Vict. c. 60, § 547). In Scotland, Admiralty suits in cases not exceeding the value of £25 are exclusively tried in the Sheriff's Court; while over that limit the Sheriff's Court and the Court of Session have concurrent jurisdiction.

By the Act 1 and 2 Geo. IV. c. 76, an arbitral jurisdiction in cases of salvage was given to certain commissioners of the Cinque Ports.

The appeal from county courts and commissioners is to the High Court of Justice, and is exercised by a divisional court of the Probate, Divorce, and Admiralty Division. In cases arising within the Cinque Ports there is an optional appeal to the Admiralty Court of the Cinque Ports. The appeal from the High Court of Justice is in ordinary Admiralty matters, as in others, to the Court of Appeal, and from thence to the House of Lords. But it is specially provided by the Judicature Act 1891, as it was by the Prize Act 1864, that the appeal in prize cases shall be to the Sovereign in Council.

The unfortunate provisions of the Legislature, giving to the jurisdiction of county courts different money limits in Admiralty, Equity, and Common Law cases, make the distinction between cases coming under the Admiralty jurisdiction and other civil cases of practical moment in those courts. Arguments full of learning and research have been addressed to the courts, and weighty decisions

have been given, upon questions which would never have arisen if the county courts had not a larger money area of jurisdiction in Admiralty cases than they have in other matters (*Reg. v. Judge of City of London Court*, 1892, 1 Q.B. 273; The "Zeta," *Civil Jurisdiction*, 1893, *App. Cas.* 468). But as regards the high courts, whether in England, Scotland, or Ireland, it is not now necessary to distinguish their civil Admiralty jurisdiction from their ordinary civil jurisdiction, except for the purpose of seeing whether there can or cannot be process *in rem*. Not that every Admiralty action can of right be brought *in rem*, but that no process *in rem* lies at the suit of a subject unless it be for a matter of Admiralty jurisdiction—one, for instance, that could in England have been tried in the High Court of Admiralty. Now these matters of Admiralty jurisdiction with process *in rem* range themselves under four primary and four supplementary heads. The four primary are damage, salvage, bottomry, wages; and the four supplementary are extensions due to one or other of the statutes 3 and 4 Vict. c. 65, and 24 Vict. c. 10. They are damage to cargo carried in a ship, necessities supplied to a ship, mortgage of ship, and master's claim for wages and disbursements on account of a ship. In all these cases, primary and secondary, the process of which a plaintiff can avail himself for redress, may be either *in personam* as in other civil suits, or by arrest of the ship, and, in cases of salvage and bottomry, the cargo. Whenever, also, the ship can be arrested, any freight due can also be attached, by arrest of the cargo to the extent only of the freight which it has to pay. For the purpose of ascertaining whether or not process *in rem* would lie, there have been distinctions as nice, and the line of Admiralty jurisdiction has been drawn as carefully, as in the cases of the Admiralty jurisdiction of the county courts (The "Theta," 1894, *Prob.* 280; The "Gas Float Whitton," 1897, *App. Cas.* 337). There have been similar questions raised in the United States, from *De Lovio v. Boit* (1815, 2 Gallison, 398), and *Ramsay v. Allegre* (1827, 12 Wheaton, 611), down to the quite modern cases which will be found quoted in the arguments and judgments in the "Float Whitton."

The disciplinary jurisdiction at one time exercised by the Admiralty Court, over both the royal navy and merchant vessels, may be said to be obsolete in time of peace, the last remnant of it being suits against merchantmen for flying flags appropriate to men-of-war (The "Minerva," 1800, 3 C. Rob. 34), a matter now more effectively provided against by the Merchant Shipping Act, 1894. In time of war, however, it was exercised in some instances as long as the Admiralty Court lasted, and is now in consequence exercisable by the High Court of Justice (see *Prize* below). It was, perhaps, in consequence of its ancient disciplinary jurisdiction that the Admiralty Court was made, and the High Court of Justice now is, the court to enforce certain portions of the Foreign Enlistment Act, 1870.

Finally, appeals from decisions of courts of enquiry, under the Merchant Shipping Act, cancelling or suspending the certificates of officers in the merchant service, may be made to the Probate, Divorce, and Admiralty Division of the High Court of Justice.

The Admiralty jurisdiction in criminal matters extends over all crimes committed on board British ships on sea or tidal waters, even though such tidal waters be well within foreign territory (*Reg. v. Anderson*, 1868, L.R. 1 C.C.R. 161), but not over crimes committed on board foreign vessels upon the high seas (*Reg. v. Serva*, 1845, 1 Denison C.C., 104). Whether it extended over crimes committed on foreign ships within territorial waters of the United Kingdom, and whether a

zone of three miles round the shores of the United Kingdom was for such purpose territorial water, were the great questions raised in *Reg. v. Keyn* (The "Franconia," L.R. 2 Ex. Div. 126), and decided in the negative by the majority of the judges, rightly, as the writer of this article respectfully thinks. Since then, however, the Legislature has brought these waters within the jurisdiction of the Admiralty by 41 and 42 Vict. c. 73. Section 2 runs as follows: "An offence, committed by a person, whether he is or is not a British subject, on the open sea within the territorial waters of British dominions, is an offence within the jurisdiction of the admiral, although it may have been committed on board or by means of a foreign ship, and the person who committed such offence may be arrested, tried, and punished accordingly." By § 7 the "jurisdiction of the admiral" is defined as "including the jurisdiction of the Admiralty of England or Ireland, or either of such jurisdictions as used in any Act of Parliament; and for the purpose of arresting any person charged with an offence declared by this Act to be within the jurisdiction of the admiral, the territorial waters adjacent to the United Kingdom, or any other part of Her Majesty's dominions, shall be deemed to be within the jurisdiction of any judge, magistrate, or officer." And "territorial waters of Her Majesty's dominions" are defined as "in reference to the sea, meaning such part of the sea adjacent to the coast of the United Kingdom, or the coast of some other part of Her Majesty's dominions, as is deemed by international law to be within the territorial sovereignty of Her Majesty; and for the purpose of any offence declared by this Act to be within the jurisdiction of the admiral, any part of the open sea within one marine league of the coast, measured from low-water mark, shall be deemed to be open sea within the territorial waters of Her Majesty's dominions." As to those portions of the sea and tidal waters which, by reason of their partially land-locked positions, are deemed to be in the body of a county, there is not Admiralty jurisdiction, but crimes are tried as if they were committed on land within the same county.

Pirates, whatever flag they pretended to fly, were, from 1360 onwards, wherever their crimes were committed, subject to the Admiralty jurisdiction. The criminal jurisdiction of the Admiralty was first exercised by the High Court of Admiralty; and then, by virtue of 28 Hen. VIII. c. 15, transferred to commissioners appointed under the great seal, among whom were to be the admiral or admirals, his or their deputies. Admiralty sessions were held for this purpose till 1834. Admiralty criminal jurisdiction is now, by virtue of the series of statutes 39 Geo. III. c. 37, 4 and 5 Will. IV. c. 36, 7 and 8 Vict. c. 2, and the criminal law consolidation Acts passed in 24 and 25 Vict. c. 1, exercised by the Central Criminal Court and by the ordinary courts of assize. Special provision for trial in the colonies of offences committed at sea has been made by 11 and 12 Will. III. c. 7, 46 Geo. III. c. 54, and 12 and 13 Vict. c. 96.

The Admiralty Court had jurisdiction in matters of prize from very early times; and although since the middle of the 17th century the *instance*, or ordinary civil jurisdiction of the court, has been kept distinct from the *prize* jurisdiction, they were originally both administered and regarded as being within the ordinary jurisdiction of the Lord High Admiral. The early records of the Admiralty show that the origin of the prize jurisdiction is to be traced to the power given to the court of the admiral to try cases of piracy and "spoil," *i.e.*, captures of foreign ships by English ships. The earliest recorded case of spoil tried before the admiral is in 1357, when the goods of a Portuguese subject, taken at sea by Englishmen from a French ship which had

previously spoiled a Portuguese, were awarded by the admiral as good prize to the English captors; and Edward III. in a letter to the king of Portugal answering a complaint on the subject gives the admiral's decision as a reason for refusing their restoration. During the 16th century a very large part of the business of the Admiralty Court related to spoil and piracy, and the Privy Council often directed the judge of the court how to deal with the spoil cases, with regard to which foreigners who had suffered from attacks by English ships made petition for redress to the admiral or the council. The spoil suit at this time (*causa spolia*) was a civil proceeding resulting in a decree *absolutoria*, dismissing the defendant, or *condemnatoria*, ordering restoration to be made by him. In 1585 the patent of Howard, the Lord High Admiral, authorized him to issue letters of reprisal against Spain; and an Order in Council regulating the conduct of those to whom such letters were issued, provided by an additional article (1589) that all prizes were to be brought in without breaking of bulk for adjudication by the Admiralty Court. The court was also resorted to at this time by captors, sailing under commissions granted by the allies of England, such as the king of France and the Dutch. About the middle of the 17th century separate sittings of the Court for Instance and Prize business began, perhaps because of the conflicting claims to *droits* of Charles II. and the duke of York as Lord High Admiral; and privateering under royal commission took the place of the former irregular "spoiling." The account which Lord Mansfield gave of the records of the Admiralty Court, that there were no prize act books earlier than 1641, or prize sentences earlier than 1648, and that before 1690 the records were in confusion, must be qualified by the fact that there are in existence prize sentences (on paper, not parchment) as early as 1589.

Although the courts of Common Law hardly ever seem to have interfered with or disputed the Admiralty prize jurisdiction, its exclusive nature was not finally admitted till 1782; but long previously royal ordinances (1512, 1602) and statutes (13 Car. II. c. 9, giving an alternative of commissioners, 22 and 23 Car. II. c. 11, 6 Anne, c. 13) had given the Admiralty Court the only express jurisdiction over prize. The same statute of Anne, and 13 Geo. II. c. 4, and 17 Geo. II. c. 24, give prize jurisdiction to any Court of Admiralty, and the Courts of Admiralty for the colonies and plantations in North America.

It has been a disputed question whether the prize jurisdiction of the court was inherent, *i.e.*, coming within the powers given by the general patent of the judge, in which no express mention of it is made, or whether it required a special commission. Upon this subject the judgment of Lord Mansfield in *Lindo v. Rodney* (1782, Dougl. 612), the judgment of Mr Justice Story in *De Lovio v. Boit* (1815, 2 Gallison, 398), and Mr Marsden's *Select Pleas of the Court of Admiralty* (introduction), may be consulted. But the settled practice now and for a long time past has been for a special commission and warrant to be issued for this purpose. In connexion with this it is observable that in 1793 the Admiralty Court of Ireland claimed to exercise prize jurisdiction under its general patent; and it is said to have been the opinion of Sir W. Wynne that the Admiralty of Scotland had a similar right (Brown, *Civil Law of Admiralty*, vol. ii. 211, 212). Any jurisdiction of the Scottish Admiralty Court over prize of war was transferred to the English court by 6 Geo. IV. c. 120, § 57. As to the Irish court, by the Act of Union it was provided that there should remain in Ireland an Instance Court of Admiralty for the determination of causes civil and maritime only.

In 1864 the constitution and procedure of prize courts,

which had until then been prescribed by occasional Acts passed for each war as it arose, were for the first time made permanent by the Naval Prize Act, by which the High Court of Admiralty and every Admiralty or Vice-Admiralty Court, or any other court exercising admiralty jurisdiction in British dominions, if for the time being authorized to exercise prize jurisdiction, were made prize courts. The High Court of Admiralty was given jurisdiction throughout British dominions as a prize court, and, as such, power to enforce any order of a Vice-Admiralty prize court and the judicial committee of the Privy Council in prize appeals—this power *mutatis mutandis* being also given to Vice-Admiralty prize courts. An appeal was given from any prize court to the Sovereign in Council. Prize courts were given jurisdiction in cases of captures made in a land expedition or an expedition made conjointly with allied forces, and power to give prize salvage on recaptured ships and prize bounty; and a form of procedure was prescribed. The High Court was also given exclusive jurisdiction as a prize court over questions of ransom and petitions of right in prize cases, and power to punish masters of ships under convoy disobeying orders or deserting convoy. By the Naval Discipline Act, 1866, power to award damages to convoyed ships exposed to danger by the fault of the officer in charge of the convoy was also given to the High Court. Under other statutes it had power to try questions of booty of war when referred to it by the Crown, in the same way as prize causes, and claims of King's ships for salvage on recaptures from pirates, which could be condemned as *droits* of Admiralty, subject to the owner's right to receive them on paying one-eighth of the value, and also power to seize and restore prizes captured by belligerents in violation of British neutrality, or by a ship equipped in British ports contrary to British obligations of neutrality.

All jurisdiction of the High Court of Admiralty has since passed to the High Court of Justice, which is made a prize court under the Naval Prize Act, with all the powers of the Admiralty Court in that respect; and all prize causes and matters within the jurisdiction of that court as a prize court are assigned to the Probate, Divorce, and Admiralty Division; and an appeal from it as a prize court lies only to the King in Council (Judicature Acts, 1873 and 1891).

By an Act of 1894 further provision is made for the constitution of prize courts in British possessions. A commission, warrant, or instruction from the Crown or the Admiralty may be issued at any time, even in peace; and upon such issue, subject to instructions from the Crown, the vice-admiral of the possessions on being satisfied by information from a Secretary of State that war has broken out between Great Britain and a foreign State, may make proclamation to that effect, and the commission or warrant comes into effect. The commission or warrant may authorize a Vice-Admiralty Court or Colonial Court of Admiralty to act as a prize court, or establish a Vice-Admiralty Court for that purpose, and may be revoked or altered at any time. The court is authorized to act as a prize court during the war, and shall after its conclusion continue to act as such, and finally dispose of all matters and things arising during the war, including all penalties and forfeitures incurred therein. Rules of court may also be made by Order in Council for regulating, subject to the Naval Prize Act, the procedure and practice of prize courts under that Act, the duties and conduct of their officers and practitioners, and the fees and costs therein (57 and 58 Vict. c. 39, §§ 2, 3). This latter power has been exercised; and prize rules for the High Court of Justice and the Vice-Admiralty prize courts were framed in 1898 (Statutory Rules and Orders, 1898).

United States.—Jurisdiction in admiralty proceedings is exclusively vested in the federal courts of the United States. The remedy in admiralty is much more extensive than in England (*Insurance Company v. Dunham*, 11 Wallace's Reports, 1). Where the common law affords another mode of action, either can be pursued. The term "admiralty" covers both civil and criminal causes, and is not limited to strictly maritime affairs. The great lakes and rivers are subject to it equally with the sea (*United States Revised Statutes*, title LXX. chap. iii.; 26 *Statutes at Large*, 424). The test is not whether the waters are tidal, but whether they are navigable. A jury may be demanded in certain civil causes (see *Revised Statutes*, 566). The States cannot create maritime liens, nor can State courts enforce them. States can create liens of a non-maritime character on vessels, and the United States Courts of Admiralty may enforce them by *in rem* proceedings (The "Glide," 167 *United States Reports*, 606). A merchantman at sea occupies the position, as to property rights, of a floating portion of the territory of the State to which he belongs (*Crapo v. Kelly*, 16 Wallace's Reports, 610). The English International Rules of 1880 were adopted by the United States in 1885. In the United States, waters are held to be within the body of a county though not so land-locked that objects can be distinctly seen by one looking from one shore to the other with the naked eye (*Manchester v. Massachusetts*, 139 *United States Reports*, 240, 263). The District Court of the United States is its court of admiralty of original jurisdiction.

Admiralty Islands. See NEW GUINEA.

Adoni, a town of British India, in the Bellary district of Madras, 307 miles from Madras by rail, has manufactures of carpets, silk, and cotton goods, and three factories for ginning and pressing cotton. The hill-fort above, now in ruins, was an important seat of government in Mahommedan times, and is frequently mentioned in the wars of the 18th century. Population, about 26,000.

Adowa, or ADUA. See ABYSSINIA.

Adrar. See SAHARA.

Adrian, a city of Michigan, U.S.A., the capital of Lenawee county, situated on the south branch of Raisin river, in the southern part of the state, 30 miles northwest of Toledo, at an altitude of 810 feet. Its plan is somewhat irregular; it is divided into five wards; and it is entered by three railways. Adrian college is a well-known Methodist institution. The population in 1880 was 7849; in 1890 it was 8756, and in 1900 it was 9654.

Adrianople, a city of European Turkey, 141 miles W.N.W. of Constantinople. It suffered heavily by the Russian occupation in 1878, not only through the dislocation of its commerce, but also through the extensive emigration to Asia Minor of the Mahommedan lower classes—a movement which so diminished the labour power of the province that agriculture, its staple industry, was paralysed, and a large area of land fell out of cultivation. This mischief was partially remedied after the annexation (1885) of Eastern Rumelia to Bulgaria, when a large proportion of the Mahommedan inhabitants of the detached province came to settle in and around Adrianople; but this advantage was more than counterbalanced by

other consequences of the territorial change. In 1892, when the last census was taken, the population numbered 85,780. Little reliance, however, can be placed on a Turkish census, the figures of which are always exaggerated. The most competent residents estimate the present (1901) population at between 66,000 and 70,000. In point of structure Adrianople is thoroughly oriental—a mass of mean, irregular wooden buildings, threaded by narrow tortuous streets, with a sprinkling of edifices of superior class. Of these the most important are the Idadieh school, the school of arts and crafts, the Jewish communal school; the Greek college, Zappeion; the Imperial Ottoman Bank and Tobacco Regie, a fire-tower, a theatre, palaces for the prefect of the city, the administrative staff of the 2nd Army Corps, and the defence works commission, a handsome row of barracks, a military hospital, and a French hospital. All these are sightly structures; but they make little show amid their squalid surroundings.

Adrianople has five faubourgs, of which Kiretchhané and Yilderim are on the left bank of the Maritza, and Kirdjik stands on a hill overlooking the city. The two last-named are exclusively Greek, but a large proportion of the inhabitants of Kiretchhané is Bulgarian. These three suburbs—as well as the little hamlet of Demirtash, containing about 300 houses all occupied by Bulgars—are all built in the native fashion; but the fifth suburb, Karagatch, which is on the right bank of the Maritza, and occupies the region between the railway station and the city, is western in its design, consisting of detached residences in gardens, many of them handsome villas and all of them comely structures of modern European type. In all the communities schools have multiplied, but the new seminaries are of the old non-progressive type. The only exception is the Hamidieh school for boys—a government institution which takes both boarders and day-scholars. Like the Lyceum of Galata Serai in Constantinople, it has two sets of professors, Turkish and French, and a full course of education in each language, the pupils following both courses. The several communities have each their own charitable institutions, the Jews being specially well endowed in this respect. The Greeks have a literary syllogos, and there is a well-organized club to which members of all the native communities, as well as many foreigners belong. The economic condition of Adrianople—city and province—was much impaired by the war of 1877-78, and was just showing signs of recovery when the severance from it of Eastern Rumelia by a Customs cordon rendered the situation worse than ever. Theretofore Adrianople had been the commercial *entrepôt* for the whole of Thrace, as it had been also, prior to the war, for a large proportion of the region between the Balkans and the Danube, now Bulgaria. But the separation of Eastern Rumelia isolated Adrianople, and transferred to Philippopolis at least two-thirds of its foreign trade which, as regards sea-borne merchandise, is carried on through the port of Burghas. Sericulture, which prior to the war contributed largely to the prosperity of the town, suffered severely for a time, but about 1890 it began to show signs of revival which gradually developed. In 1897 and 1898 the output of silk increased in a remarkable degree, and in 1899 the crop equalled those of the most prosperous period which the silk industry has ever known in Adrianople. Unfortunately, the failure of the grain crops of the province in 1900 and in the four previous years almost neutralized the effect of these good silk harvests on the general prosperity of the population. The production of cheese continues steadily to increase. During the last few years great pains have been bestowed upon the improvement and extension of the fortifications, with the object of rendering them impregnable. In the opinion of military experts this object has been attained.

(E. W.*)

Adriatic. See MEDITERRANEAN.

Adullam, a city in the "lowland" of Judah, now Áid el-Ma, 7 miles north-east of Beit-Jibrín. The cave was near the city, and not near the Dead Sea. As a political expression the "cave of Adullam" first occurs in a Reform speech by Mr Bright in 1866.

Adulteration.—So many difficulties had been met with in the operation of the Adulteration of Food Act 1872, referred to in the ninth edition of this work, together with the Act of 1860, that in 1874 a Select Parliamentary Committee was appointed, which, after hearing much evidence, reported that, while the Act had done much good, it had at the same time inflicted considerable

injury and enforced heavy and undeserved penalties upon some respectable tradesmen. "This appears to have been mainly due to the want of a clear understanding as to what does and what does not constitute adulteration, and in some cases to the conflicting decisions and inexperience of the analysts. Your committee are of opinion that the Act itself is defective and needs amendment." The Act had been but very partially applied; in most districts it had not been put into operation at all, in many no analysts had been appointed, in others no inspectors whose duty it would have been to purchase samples and submit them to the analysts for analysis. At that time but very few chemists had a competent knowledge of the composition of articles of food and of drink. The work in previous years had been carried on by amateurs, microscopists, and sensation-mongers, and no systematic steps had been taken to collect trustworthy analyses and to work out efficient and practicable methods of analysis. Upon the report of the Select Committee of 1874 the Sale of Food and Drugs Act 1875 was based, all previous Acts being repealed. This Act avoided the term "adulteration" altogether, and endeavoured to give a general definition of "food," of "drug," and of offences which would bring dealers in food and drugs into collision with the Act. The appointment of analysts was made incumbent upon the City of London, the vestries, all county quarter-sessions, and town councils of boroughs having a separate police establishment, and inspectors were empowered to collect samples for analysis. For the protection of the vendor such samples as were purchased for analysis were to be offered to be divided into three parts, one to be submitted to the analyst, the second to be given to the vendor to be dealt with by him as he might deem fit, whilst the third was to be retained by the purchasing inspector, and, at the discretion of the magistrates hearing any summons, to be submitted, in case of dispute, to the Commissioners of Inland Revenue for analysis by the chemical laboratory at Somerset House. The public analyst had to give a certificate to the person submitting any sample for analysis, which certificate was to be taken as evidence of the facts therein stated, in order to render the proceedings as inexpensive as possible. If the defendant in any prosecution proved to the satisfaction of the court that he had purchased the article under a warranty of genuineness, and that he sold it in the same state as when he purchased it, he was to be discharged from the prosecution, but no provision was made that in that event the giver of the warranty should be proceeded against. For admixing injurious substances with food or drug a fine not exceeding £50 could be imposed, or, after a conviction for a first offence, imprisonment for a period not exceeding six months with hard labour. For any ordinary practice of sophistication the maximum fine was fixed at £20.

The general definition above referred to, contained in clause 6 of the Act, was couched in the following words:—"No person shall sell to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser; provided that an offence shall not be deemed to be committed in the following cases:—(1) Where any matter or ingredient not injurious to health has been added to the food or drug because the same is required for the production or preparation thereof as an article of commerce, in a state fit for carriage or consumption, and not fraudulently to increase the bulk, weight, or measure of the food or drug, or conceal the inferior quality thereof; (2) where the food or drug is a proprietary medicine or is the subject of a

patent in force; (3) where it is compounded in accordance with the demand of the purchaser; and (4) where the food or drug is unavoidably mixed with some extraneous matter in the process of collection or preparation." This clause soon gave rise to an immense amount of litigation, and already in 1879 it was found necessary to pass a short Amendment Act, making it clear that if a purchase was effected by an inspector with the intent to get the purchased sample analysed he was as much "prejudiced" if obtaining a sophisticated article as a private purchaser who purchased an article for his own use and consumption. In the practical carrying out of the Act the chief difficulty was soon found to consist in ascertaining whether any article was "of the nature, substance, and quality demanded by the purchaser." This, on superficial consideration, seems to be a very simple matter. Thus, if a vendor supplies a customer who demands "milk" with milk and water, or with milk from which a part of the cream has been removed by skimming, it may appear to be a very easy task to ascertain whether the purchaser's demand has been complied with or not. But the composition of milk as yielded by the cow varies widely under different conditions, with the race and breed of the animal, its food, state of health, the period of lactation, the time of year, climate, &c. Thus, while a good Jersey cow might yield milk with 8 per cent. of fat, a Dutch cow might have but $2\frac{3}{4}$ or 3 per cent. of fat in its milk, and a great portion of the fat from the former might be removed before it fell to the level of the latter. Were the analyst to insist upon a standard of fat equal to that present in the best milk, many, even the majority of, genuine samples would have to be condemned, while, if he adopted the lowest recorded limit found in genuine milk, cream might be removed from almost all milk of normal nature, to the great damage of farmers and of the public. Similarly, but not quite to the same degree, there is a variation in the amount of the other food-constituents of milk, the so-called "solids-not-fat" or non-fatty solids, from the quantity of which the analyst concludes whether water has been added to the milk. It is obviously impossible to differentiate between the water which is natural to pure milk, and which constitutes the greater part of it, and between water that may have been fraudulently added to the article; but by the addition of water the constituents upon which the food-value of milk is dependent become depressed, and the depression is naturally in proportion to the quantity of added water. It required the united efforts of public analysts, who in 1875 founded the Society of Public Analysts, to ascertain by many tens of thousands of analyses of samples of milk the natural variation of the composition of milk, and to fix reasonable and fair limits applicable to pure milk. The milk yielded by single cows varies widely, and it is almost impossible to state the extremes, but the milk supplied to the public by vendors is almost invariably the mixed product of a herd, and extremes are equalized by such mixing. A monumental record of the composition of mixed milk was made by Dr Paul Vieth, who in 1892 published results of no less than 120,540 analyses of genuine milk, showing that the average composition varied in such manner that the percentage of fat was highest in September, October, and November, and lowest in June and July, while the proportion of "solids-not-fat" was subject to comparatively little variation, and that the numbers adopted by public analysts previously, namely, 3 per cent. for fat and 8.5 per cent. for solids-not-fat, were fair and equitable. Further reference will be found on this subject under the sub-heading "Milk" below. Similar difficulties are met with in all other articles of food, and, in fact, with annually extending experience, wider and wider variations in

composition have been found, continually adding to the difficulty of arriving at a fair conclusion upon the basis of analysis. It may be said that a purchaser who obtains milk of extreme poverty, however untampered with, is prejudiced, because he expects to obtain milk of at least average quality, but the Food Acts are intended to repress and punish fraud only. While, however, milk vendors at first strongly opposed the use of more or less arbitrary limits of composition insisted upon by the executive officers, they slowly recognized that both the interest of the public and their own required them, and of late the raising of the limits has been favourably looked upon by some of the largest milk-vendors. By law no limit or standard is recognized at the present time, but a committee appointed by the Board of Agriculture have carefully inquired into the matter, and have recently reported officially recommending limits for the composition of milk, setting at rest a question which, since 1875, has given rise to a vast amount of labour and to numberless disputes.

A curious condition of things arose out of the definition of "food" as given in the Sale of Food Act 1875. "The term 'food' shall include every article used for food or drink by man, other than drugs or water." It had been the practice of bakers to add alum to the flour from which bread was manufactured, in order to whiten the bread and to permit the use of damaged and discoloured flour. This practice had been strongly condemned as early as the middle of the century by Liebig, as rendering the bread indigestible and injurious to health. Very shortly after the passing of the Food Act this objectionable practice disappeared, and alumed bread now no longer occurs. A large trade, however, continued to be carried on in baking powders consisting of alum and sodium bicarbonate, mainly used in private households. It was naturally thought that, as baking powder is sold with the obvious intention that it may enter into food, the vendors could also be proceeded against and the noxious trade stamped out. A strongly contested case having come before the High Court (*James v. Jones*) from the Swansea County Bench, it was held that baking powder was not an article of food, and that it was not an offence within the Food Acts to sell alumed baking powder. Following this decision it was obvious that spices, like pepper, cayenne, &c., were also not articles of food, and a further amendment of the law became inevitable. Before referring to the passing of the amended Act, which came into force in 1899, consideration must, however, be given to another fragment of piecemeal legislation, the Margarine Act of 1887. As early as the sixth decade of the 19th century substitutes for butter had been tried and had found a small market, mainly on the Continent. During the siege of Paris their manufacture received a powerful impulse, and soon after 1870 imitation-butter began to be sold in increasing quantities under the name of *Margarine*. "butterine." This consisted of the softer portion of beef and other fats, coloured in imitation of butter, and churned with milk, often also flavoured with butter. The chief seat of manufacture of the article was, as it still is, in Holland, the raw material coming mostly from the United States. Although imported as an article essentially different from butter, its appearance, consistency, and name invited its substitution for real butter at the hand of unscrupulous traders; and there is no doubt that immense quantities of "butterine" were sold to the public as butter, to the great damage of farming and legitimate trade interests. Again a parliamentary committee sat and took evidence, and it was resolved to give a new name to the article, that of "margarine" (first given by Chevreul to a substance isolated by him from fats in beautiful pearly crystals), and to compel

the labelling and branding of all boxes and vessels in which the article was conveyed and stored, as well as the marking of the papers in which the retail dealer sold it, with the word "margarine," even mixtures of the substitute with real butter coming under that obligation. It was probably hoped that by these means the trade in butter-substitutes might be checked or destroyed, but the contrary happened, the new name soon taking root, and the sale of the article increasing by leaps and bounds, in spite of the great rate of increase in the import of genuine butter. Thus the Margarine Act ran conjointly with the original Food Act of 1875 and the Amendment Act of 1879. The result was a further increase in modifying decisions of High Courts and increasing difficulty in interpreting the meaning of the Acts. Growing dissatisfaction was expressed by the vendors, wholesale and retail, and by the authorities who had to see the Acts enforced, and the outcome of much agitation was once more a parliamentary committee, appointed in 1894, and reappointed in 1896 and 1897, voluminous evidence being taken and considered, resulting finally in a fourth Act, the Sale of Food and Drugs Act 1899, again superimposed over the three prior pieces of legislation.

and Drugs Act 1875, broadly speaking, there cannot be any doubt. The preceding table, taken from the Report of the Local Government Board for 1900, shows clearly that the percentage of adulterated articles has steadily declined since 1877 from 19 per cent. of all samples analysed to 9 per cent.

The effect, gratifying as it is, would have been still greater if many towns and districts had not neglected, in spite of pressure brought to bear upon them by Government and others, to put the Acts into operation. The Acts compel the authorities to appoint analysts, but until the Act of 1899 no means existed to force unwilling councils to collect samples for analysis, or in many cases only so small and insignificant a number that food control was virtually non-existent. As far, however, as statistics are available, figures prove that in districts where the Acts are more or less feebly administered the proportion of adulteration is greater than in others that vigorously apply the legal means for repressing fraud. Thus in 1890, Somersetshire, working the Acts efficiently, took one sample for analysis per annum for every 379 inhabitants, and the percentage of adulterated articles found was only 3·6, or only about one-third of the amount representing the average for the whole country. Gloucestershire, with one sample for 770 inhabitants, had 6·2 per cent. of adulteration; Hampshire, with one sample for 1224 inhabitants, 12·2 per cent.; Derbyshire, with one sample for 3164 inhabitants, 17·1 per cent.; Oxfordshire, with only one sample for 14,963, no less than 41·7 per cent. of adulterated articles. Even in 1899 no samples whatever were officially analysed in seven English boroughs, while within the jurisdiction of six counties and seven boroughs, with a total population of 600,000, only 139 samples were analysed during the year, and in 65 other districts the proportion examined was less than was deemed sufficient by the Local Government Board. The public authorities, at the same time, recognize in most cases the material public benefit conferred by the various enactments. In 1899, 53,056 samples were examined by public analysts: 4970 were reported against, and proceedings were instituted against 3110 vendors—fines amounting to £6258 being imposed.

Working of the Acts.

Year.	Number of Samples.		Percentage of Adulteration.	Average percentage in Quinquennial Periods.
	Examined.	Adulterated.

The increased vigilance on the part of the public officers is met by an increased application of science to adulteration. Thus, for some years the substitution of margarine for butter, an unabashed fraud, was common. The substitution, owing to advance in methods of chemical analysis, being readily discoverable since 1874 and punished, mixtures of butter with gradually decreasing percentages of margarine were made and sold; and at the present time large quantities of mixtures, containing not more than 8 to 10 per cent. of margarine, are freely imported from abroad and sold as "warranted pure" butter, the mixing being done with the assistance of skilled chemists, who, knowing the composition of the pure article, carefully let it down by the addition of margarine to such a point that the mixture still possesses the characters of pure, though slightly abnormal butter, against which proceedings could not be undertaken with probability of conviction of the vendor. Margarine, specially adapted for this fraud, is made by Dutch manufacturers. In milk, similarly, the skilful vendor, knowing the natural variations of milk, dilutes or skims it to the exact point which experience has shown to render him reasonably safe from detection. The whole of the information contained in analytical literature, primarily for the benefit of the analyst, is available to the fraudulent manufacturer, and no new process of analysis appears without immediate effort on the part of the mixer to circumvent and defeat it. Two practices which

Scientific adulteration.

As to the working of the highly complicated machinery thus created since 1st January 1900 it is yet too early to speak, but of the beneficial results of the Sale of Food

are closely akin to adulteration, if not actually such, have much engaged the attention of analysts during the last few years—namely, the addition of chemical preservatives and of colouring matters to articles of food. Chemical preservatives are contained in many perishable articles—namely, sulphite of lime in beer, syrups, meat, lime-juice, &c.; salicylic acid sometimes in wines and often in jams; formaldehyde (formaline) in milk. But by far the most frequently used materials are borax and boracic acid, almost universally present in imported butter (with the exception of Danish butter), and in much that is made in Great Britain, in cured ham, in fish, cream, and milk. A preservative acts as a bactericide and in no case is physiologically inert, although the dose taken at a meal may not be sufficient to produce obvious effects. Medical opinion is, however, at present almost unanimous that the continual use of preservatives cannot fail to be injurious to the human system, and the increasing infant mortality in some towns is attributed to the fact that the milk used by the infants is now so frequently borated. A Committee appointed by the Board of Agriculture has been engaged on this subject, but at the time of writing no report has yet been made public. The employment of preservatives is justified by dealers in perishable articles by pointing to the difficulty which would otherwise be experienced in collecting in distant countries food-materials like butter, shipping them to England, and distributing them to the public without loss of quality; on the other hand, modern means of preserving food, in cold-store, &c., are being pointed to as fully sufficient to meet all wants without the introduction of foreign matters.

Colouring matters, quite harmless in themselves, are largely used at the present time in many articles of food and drink. Originally the use of a yellow dye in milk was due to a fraudulent motive, namely, to hide the blueness produced by watering. Gradually the public, especially in London, became accustomed to see their milk of a distinct yellow tint, and all milk, even genuine milk free from added water, sold in London, is now coloured, generally with anatto, often with aniline dye; and it would be almost impossible for a vendor to sell milk of its natural colour. Again, all butter sold in London and the South of England is coloured yellow. Natural butter has often a very faint fawn tint, and the public, educated to see butter yellow, would not purchase such butter; hence the now universal colouring adopted. The Food Act cannot cope with this practice, as long as the object of colouring is not a fraudulent one and the colour itself is harmless. The colouring of preserved peas by the use of a little copper sulphate is on a different basis, as the copper is considered liable to produce injury to health, and many vendors of coppered peas have been fined during recent years; yet the public object to purchase preserved peas of the natural brown colour. Jams are very frequently dyed, and the brilliantly coloured jams now sold owe most of their colour to coal-tar dyes, which are often employed to hide the fact that unripe or inferior fruit has been used by the manufacturer.

We will now consider recent forms of adulteration in specific articles, and the means adopted for their detection.

Milk.—Although the general qualitative composition of milk has been known for very many years, all quantitative statements concerning the proportion of the several constituents published before 1884 are affected with considerable errors. About 1872 Wanklyn showed that, although, as was well known, the percentage of the fat of milk was subject to very considerable fluctuation, when the percentage of milk-sugar, caseine, and other albuminoids and mineral water was added together, the “solids-not-fat”

varied but little, and he proposed to utilize that fact to determine whether milk was genuine or had been impoverished by the addition of water,—it being evident that water would diminish the percentage of solids-not-fat, the percentage of addition being readily calculated from the amount of the latter. Although the method of ascertaining the proportion of “solids-not-fat” adopted by Wanklyn has been shown to be somewhat erroneous, the principle of analysis established by him has remained the basis upon which milk-analysis rests, and public analysts virtually adopted the limits proposed by him—viz., 2·5 per cent. of fat and 9 per cent. of solids-not-fat. In 1884 M. A. Adams showed, however, that the then usual method of analysis did not allow of the complete removal of the fat from the other milk-constituents, that therefore the proportion of fat had been underestimated, the amount of the solids-not-fat being correspondingly too high. By the simple and ingenious expedient of spreading a known volume of the milk to be analysed upon a long strip of blotting-paper and extracting the paper together with the dried milk by a solvent, such as ether or benzene, the fat could be completely removed from all other constituents. After full investigation the Society of Public Analysts altered the limits, in accordance with the new discovery, to 3 per cent. as a minimum for the fat and 8·5 per cent. for the solids-not-fat. As the average composition of genuine milk, according to Vieth, is 4·1 per cent. of fat, 8·8 of solids-not-fat, and 12·9 per cent. of total matter other than water, it is obvious that the limits allow for a reasonable departure from the average. The Board of Agriculture's Departmental Committee has quite recently issued a report, in which the following recommendations are made as to proportions of food constituents which should be present in milk. The percentage of total solids must not be less than 12, the proportion of solids-not-fat not less than 8·5 per cent., and that of fat at least 3·25. If the amounts are smaller, a presumption is raised, unless the contrary is proved, that the milk is adulterated by skimming or watering. The recommendations of the Committee are most valuable, as tending to the improvement in the breed of dairy cattle, and cows yielding milk poorer than the above will probably be weeded out and replaced by superior breeds. A number of means are now known allowing of the complete analytical separation of the fat other than the “Adams” method. The “galactometer” and “lactometer” instruments, referred to in the article in the ninth edition of this work, have long been abandoned. Other far more exact and more rapid means have been found to determine the composition of milk with a degree of accuracy sufficient for practical, especially dairying, purposes. As the fat of milk is its most valuable and most important constituent, it is of high importance to the butter-producer in particular to know the exact proportion of the fat, partly in order to know that he obtains value for his money, and also to check the efficiency of the working of his appliances for separating the cream—centrifugals being now universally employed for that purpose. By centrifugal force alone the fat globules of milk do not coalesce into a layer of pure fat; if, however, an acid, like hydrochloric or sulphuric acid, be added to the milk in sufficient quantity prior to subjecting it to centrifugal force a clear layer of pure butter-fat separates, and if a measured quantity of milk be taken and the volume of the separated fat be determined, generally in a graduated glass-tube, the amount of fat in any sample of milk can be arrived at in a few minutes. Upon this principle a number of instruments have been designed and render excellent service in the creamery and laboratory. As, moreover, a definite relation exists between the specific gravity of a milk and its contents in fat and solids-not-fat, it follows that the

specific gravity of a milk being known and its contents in fat, the proportion of solids-not-fat can be calculated. Formulæ for that end have been worked out by a number of chemists. An analysis of milk, showing the specific gravity, the percentage of fat and that of solids-not-fat can therefore now be made in as many minutes as the hours formerly required, and in scientifically conducted dairies the price paid for the milk is regulated by the analytical data obtained.

No forms of adulteration occur except the addition of water, the removal of cream (or its equivalent, the addition of skim-milk), and, if adulteration it be, the addition of preservatives. All statements as to the occurrence of chalk and of sheep's brains are fables. Although the addition of water is still a common form of adulteration, the percentage of added water is mostly not greater than from 8 to 15, and the grosser and more impudent frauds commonly met with twenty years ago have practically been stamped out. A number of the large dairies supplying London and other large towns have fully equipped laboratories, with a staff of highly trained chemists, analysing almost each churn of milk delivered by the farmers, adulteration being thus as completely prevented as possible. Against the skimming of milk the means available are not so effective as those against watering, as the natural variation of the amount of fat is so considerable, partially skimmed Jersey milk still containing as much fat as unaltered milk from lowland cattle.

Butter.—Since the introduction of margarine, frauds in the butter trade are exclusively confined to two kinds—namely, the substitution of margarine for and the addition of margarine to butter, and the incorporation or undue retention of water. Referring firstly to the latter form of adulteration, it must be borne in mind that all butter contains water. Properly-made butter contains, as a rule, 11 to 15 per cent.; it is not practicable to remove a larger proportion by rolling or squeezing, as the consistency of the butter suffers; 16 or at most 17 per cent. of water may legitimately be present in good butter. If, however, the churning of the cream is carried out at too high a temperature, an emulsion of water and butter is formed, containing as much as 30 or even 40 per cent. of water, causing the article to assume an ointment-like appearance. In properly-equipped dairies, refrigeration of the cream, if needful, is adopted to reduce the temperature of the cream in summer; but in small and old-fashioned dairies, as in many of those in the West of Ireland, these means are not available, and Irish butter, therefore, often contains an excess of water, 25 per cent. and over. As in most cases magistrates have declined to consider this as an adulteration, and often enough the petty farmers are not to be blamed, the wilful introduction of water into butter has at times been carried out on an industrial scale, and even at the present time much butter is sold which has been loaded with water up to 28 and more per cent., with of course good profit to the "manufacturer."

Chemical differentiation between butter and butter-substitutes, now called margarine, was unknown prior to 1873, when the writer, with A. Angell, published a method which readily allowed of such differentiation, and of the estimation of the proportions of butter-fat and other fat contained in a mixture, based upon the fact that while fats other than butter-fat (and cocoa-nut oil) contain about 95.5 per cent. of fatty acids insoluble in water, butter-fat contains a smaller quantity—namely, about 86 to 88 per cent.—the difference being due to the presence of a corresponding amount of water-soluble fatty acids. Various modifications and simplifications of this principle have since been worked out, and the detection of margarine in butter, if present in substantial amount, has been

rendered easy and certain. In the case of butter, as in that of milk, the analyst has, however, to reckon with natural variations in the composition of the butter-fat itself, and no means have yet been discovered whereby percentages smaller than 10 per cent. can be discovered with sufficient certainty to lead to the conviction of the vendors. It is a singular fact that while, as a rule, the composition of the butter-fat is almost independent of the food of the animal, under some conditions depending mainly upon the period of lactation, the composition of the fat undergoes material changes, so that a cow in the last stages of lactation may yield milk, small in quantity, from which butter can be churned which analyses as if it were a mixture of butter and margarine. Luckily it happens but rarely in practice that all the cows of a whole herd become "dry" at the same time; hence the natural variation in composition equalizes itself as a rule. There are, however, a few cases on record, notably one carefully worked out by A. H. Allen, in which butter was made under strict supervision in Denmark from absolutely pure materials, yet analysed like a mixture. It is doubtful therefore whether adulteration of butter with small amounts of margarine can ever be quite prevented by certain discovery, especially if the admixture is made, as in some parts of Holland, with the active aid of skilled chemists. When it is considered that England imports about ten million pounds sterling worth of butter per annum, the immense importance of preventing substitution of margarine, of approximately half the price of butter, will be apparent.

Some most ingenious instruments have been constructed, notably Abbe's refractometer, with a view to obtain by physical means data for discrimination between butter and mixtures. Melted butter-fat refracts light to a less degree than do butter-substitutes; the instrument in question allows of the determination of the "index of refraction" by the use of a mere droplet of the butter-fat, and is a most valuable tool in the hands of the chemist.

Cheese.—From America cheese has come into the English market, made from skim-milk which has again been provided with fatty matter, generally emulsified margarine—hence the term "margarine cheese," or "filled cheese"—a legitimate article if sold with full disclosure of its nature, but one which readily lends itself to fraud. Cases of cheese-poisoning have been recorded, and a highly poisonous substance, termed tyrotoxin, has been extracted from cheese by Vaughan. Compounds of zinc and of lead have also been met with.

Lard.—Between the years 1880 and 1890 a gigantic, fraudulent trade in adulterated lard was carried on from America. A great proportion of the American lard imported into England was found to consist of a mixture of more or less real lard, with cotton-seed oil and beef-stearine. Cotton-seed oil is one of the cheapest vegetable oils fit for human consumption; beef-stearine, the hard residue obtained in the manufacture of oleomargarine after the more fluid fat has been pressed out from the beef-fat. So skilfully were the mixtures made that for some years their very existence escaped notice, until in 1888 a bill introduced in the American Senate to stop the imposture directed general attention to the matter, and energetic measures by the food-officers quickly put a stop to it as affecting the United Kingdom. From the memorial presented to the U.S. Senate in support of the bill, it appeared that in about 1887 the annual production of lard in the States was estimated at 600 million pounds, of which more than 35 per cent. were adulterated. During the last seven or eight years compounds have been made containing no lard or only a faint trace of lard. These compounds were sold as "refined lard," "pure refined lard," "choice refined lard," "choice refined family lard,"

and other similar names. Professor Wiley, in his evidence on the subject, said that "Messrs Armour and Co. state that they use from 59 to 75 per cent. of lard in their mixtures, Fairbank from 50 to 75 per cent. The former firm use 75,000 barrels of cotton-seed oil, and make 60 million pounds refined lard. 75,000 barrels weigh 28 million pounds: hence the average proportion would be 46 per cent. of cotton-seed oil in the mixture; but as from 10 to 15 per cent. of beef-stearine are necessary to stiffen the mixture, the proportion of lard would be only about 42 per cent."

Oils.—Since the article in the ninth edition of this work appeared, enormous progress has been made in the chemical knowledge of fats and oils, and complicated mixtures of various oils can now be satisfactorily analysed. Perhaps the most important step was taken by Allen and von Huebl, who showed that different fats and oils were capable of combining with different percentages of bromine or iodine, the "iodine-absorption" number being characteristic for each class of oils—the olive-oil group showing about 80-90 per cent.; the cotton-oil group about 105-110; linseed-oil, 160-170. This number, together with a determination of the saponification-value (the amount of caustic alkali needed for complete saponification), the thermal rise with strong sulphuric acid (Maumene), or bromine (Hehner and Mitchell), the refraction of light and the specific gravity, enable the analyst to form in most cases a close idea as to the nature of any sample under examination. The adulteration of oils has in consequence become far less. Cotton-seed oil and, latterly, the oil expressed from the maize-germ (maize oil), are the most common fatty adulterants, but much use is also made in this direction of paraffin oils and resin oil. So-called olive oil frequently consists of a mixture of olive oil, cotton-seed oil, earthnut (arachis) oil, and sesame-seed oil, one or the other of these being sometimes altogether substituted for genuine olive oil. Odourless paraffin hydrocarbons also enter into these adulterated articles.

Pepper.—Some years ago ground olive-kernels were largely sold for admixture with pepper, under the name of "poivrette." They were easily recognizable on microscopic examination and the fraud did not live long. The older forms of adulteration (rice and other farinaceous meals) also still occur.

Ginger.—The more or less exhausted ginger resulting in the manufacture of ginger beer used until lately to be re-dried, ground, and mixed with fresh ginger—a great proportion of commercial ground ginger consisting of so-called "spent" ginger. If exhausted by water the proportion of the water-soluble constituents of ginger—if by alcohol, those of the alcohol-soluble ones—were reduced by the treatment, thus affording to the analyst guidance in coming to a judgment. Similar fraud exists in the case of aromatic substances from which valuable oils can be extracted, the exhausted ground stuff being sold in admixture with the genuine.

Beer.—In 1899 an obscure illness broke out in Dublin resembling the tropical disease "beri-beri." Early in August 1900 a rapid increase in the number of "peripheral neuritis" cases, closely resembling the Dublin beri-beri cases, was observed in Lancashire. It soon became clear that there was some connexion between the drinking of beer and the obscure disease; and Dr Reynolds, Physician to the Royal Manchester Infirmary, on investigation found arsenic in the suspected beer. This discovery caused an immense amount of attention to be given to beer. Traces of arsenic were found in samples from many parts of the country; but the greatest amounts of arsenic (up to 1 grain per gallon, calculated as arsenious

acid, has been met with) were traced to the employment in a number of breweries of some starch-glucose that had been manufactured by the aid of very impure, arsenical, sulphuric acid by a Lancashire firm. Numerous deaths were due to the drinking of such arsenicated beer. It was also soon discovered that much of the malt used by brewers contained appreciable traces of arsenic, and in hops small traces were found. Malt and hops probably derive their arsenic from the fact that both are prepared by an antiquated process, the drying of both being effected by the gases and fumes which are given off by coke or anthracite fires, these fumes passing through the malt and hop, which absorb therefrom any arsenic that may be associated with the pyrites occurring in all coal. Sulphur, often arsenical, is also sprinkled upon the fires to lighten the colour of malt or hop. All the worst cases, however, of arsenic in beer were due to arsenical glucose, prepared by one firm. The use of glucose is perfectly legal, the brewer having the statutory right to brew from whatever material he may deem proper, as long as he pays due revenue to the State—the revenue being levied upon the basis of the specific gravity of the wort, every liquor under the Customs and Inland Revenue Act, 1885, being defined as beer, "which is made or sold as a description of beer, or as a substitute for beer, which on analysis of a sample thereof shall be found to contain more than 2 per cent. of proof spirit." The fact that arsenic was liable to occur in glucose and in beer was known as long ago as 1878, but no quantities in any way resembling those met with in the recent cases had previously been observed. Since the use of glucose has become general in brewing, other industrial users of sugar, principally the manufacturers of sweetmeats, jams, and syrups, have also largely employed glucose, mainly for the cheapening of their products. No doubt the strict supervision which will henceforth be exercised over the purity of glucose will render an occurrence such as that of beer-poisoning by arsenic unlikely in the future; but a strong desire has been aroused to draw a distinction by Act of Parliament between beer made from malt and hops and such as may be prepared from substitutes.

(O. H. *)

Advertisement, or advertising, as the process of purchasing publicity is now more commonly called, is of very recent origin if it be regarded as a serious adjunct to other phases of commercial activity. In some rudimentary form the seller's appeal to the buyer must, however, have accompanied the earliest development of trade. Under conditions of primitive barter, communities were so small that every producer was in immediate personal contact with every consumer. As the primeval man's wolfish antipathy to the stranger of another pack gradually diminished, and as intercourse spread the infection of larger desires, the trapper could no longer satisfy his more complicated wants by the mere exchange of his pelts for his lowland neighbour's corn and oil. A began to accept from B the commodity which he could in turn deliver to C, while C in exchange for B's product gave to A what D had produced and bartered to C. The mere statement of such a transaction sufficiently presents its clumsiness, and the use of primitive forms of coin soon simplified the original process of bare barter. It is reasonable to suppose that as soon as the introduction of currency marked the abandonment of direct relations between purchaser and consumer an informal system of advertisement in turn rose to meet the need of publicity. At first the offer of the producer must have been brought to the trader's attention, and the trader's offer to the notice of the consumer, by casual personal contact, supple-

mented by local rumour. The gradual growth of markets and their development into periodical fairs, to which merchants from distant places resorted, afforded, until printing was invented, the only means of extended advertisement. In England, during the 3rd century, Stourbridge Fair attracted traders from abroad as well as from all parts of England, and it may be conjectured that the crying of wares before the booths on the banks of the Stour was the first form of advertisement which had any marked effect upon English commerce. As the fairs of the Middle Ages, with the tedious and hazardous journeys they involved, gradually gave place to a more convenient system of trade, the 15th century brought the invention of printing, and led the way to the modern development of advertising. The Americans, to whom the elaboration of newspaper advertising is primarily due, had but just founded the first English-speaking community in the Western hemisphere when the first newspaper was published in England. But although the first periodical publication containing news appeared in the month of May 1622, the first newspaper advertisement does not seem to have been published until April 1647. It formed a part of No. 13 of *Perfect Occurrences of Every Daie* journall in Parliament, and other Moderate Intelligence, and it read as follows:—

A Book applauded by the Clergy of England, called *The Divine Right of Church Government*, Collected by sundry eminent Ministers in the Citie of London; Corrected and augmented in many places, with a briefe Reply to certain *Queries* against the Ministry of England; Is printed and published for *Joseph Hunscot* and *George Calvert*, and are to be sold at the 'Stationers' Hall, and at the Golden Fleece in the Old Change.

Among the *Mercuries*, as the weekly newspapers of the day were called, was the *Mercurius Elencticus*, and in its 45th number, published on 4th October 1648 there appeared the following advertisement:—

The Reader is desired to peruse a Sermon, Entitled *A Looking-Glasse for Levellers*, Preached at St. Peters, Pauls Wharf, on Sunday, Sept. 24th 1648, by Paul Knell, Mr. of Arts. Another Tract called *A Reflex upon our Reformers, with a prayer for the Parliament*.

In an issue of the *Mercurius Politicus*, published by Marchmont Nedham, who is described in the ninth edition of the *Encyclopædia Britannica* (see NEWSPAPERS, vol. xvii. p. 414) as "perhaps both the ablest and the readiest man that had yet tried his hand at a newspaper," there appeared in January 1652 an advertisement, which has often been erroneously cited as the first among newspaper advertisements. It read as follows:—

Irenodia Gratulatoria, a heroic poem, being a congratulatory panegyrick for my Lord General's return, summing up his successes in an exquisite manner. To be sold by John Holden, in the New Exchange, London, Printed by Thomas Newcourt, 1652.

The article "On the Advertising System," published in the *Edinburgh Review* for February 1843, contains the fullest account of early English advertising that has ever been given, and it has been very freely drawn upon by all writers who have since discussed the subject. But it describes this advertisement in the *Mercurius Politicus* as "the very first," and the discovery of the two earlier instances above quoted was due to the researches of a contributor to *Notes and Queries*.

In *The Crosby Records*, the commonplace-books of William Blundell, there is an interesting comment, dated 1659, on the lack of advertising facilities at that period—

It would be very expedient if each parish or village might have some place, as the church or smithy, wherein to publish (by papers posted up) the wants either of the buyer or the seller, as such a field to be let, such a servant, or such a service, to be had, &c. There was a book published in London weekly about the year 1657 which was called (as I remember) *The Publick Advice*. It gave information in very many of these particulars.

A year later the same diarist says—

There is an office near the Old Exchange in London called the office of Publick Advice. From thence both printed and private information of this useful nature are always to be had. But what they print is no more than a leaf or less in a diurnal. I was in this office. The diurnal consisted of sixteen pages quarto in 1689.

In No. 62 of the *London Gazette*, published in June 1666, the first advertisement supplement was announced—

An Advertisement—Being daily prest to the Publication of Books, Medicines, and other things not properly the business of a Paper of Intelligence, This is to notifie, once for all, that we will not charge the *Gazette* with Advertisements, unless they be matter of State: but that a Paper of Advertisements will be forthwith printed apart, & recommended to the Publick by another hand.

In No. 94 of the same journal, published in October 1666, there appeared a suggestion that sufferers from the Great Fire should avail themselves of this means of publicity—

Such as have settled in new habitations since the late Fire, and desire for the convenience of their correspondence to publish the place of their present abode, or to give notice of Goods lost or found, may repair to the corner House in Bloomsbury on the East Side of the Great Square, before the House of the Right Honourable the Lord Treasurer, where there is care taken for the Receipt and Publication of such Advertisements.

The earlier advertisements, with the exception of formal notices, seem to have been concerned exclusively with either books or quack remedies. The first trade advertisement, which does not fall within either of these categories, was curiously enough the first advertisement of a new commodity, tea. The ninth edition of the *Encyclopædia Britannica* (see TEA, vol. xxiii. p. 101) quotes this advertisement from the *Mercurius Politicus*, No. 435, for September 1658—

That excellent and by all Physitians approved China Drink, called by the Chineans *Tcha*, by other nations *Tay*, alias *Tee*, is sold at the Sultaneess Head, a cophee-house in Sweetings Rents, by the Royal Exchange, London.

The history of slavery, of privateering, and of many other curious incidents and episodes of English history during the 17th and 18th centuries, might be traced by examination of the antiquated advertisements which writers upon such subjects have already collected. In order that space may be found for some consideration of the practical aspects of modern advertising, the discussion of its gradual development must be curtailed. Nor is it necessary to preface this consideration by any laboured statement of the importance which advertising has assumed.

It is a matter of common knowledge that several business houses are to be found in Great Britain, and a larger number in the United States, who spend not less than £50,000 a year in advertising, while one patent medicine company, operating both in England and the United States, has probably spent not less than £200,000 in Great Britain in one year, and an English cocoa manufacturer is supposed to have spent £150,000 in Great Britain. Some of the best works of artists as distinguished as Sir John Millais, Professor Herkomer, and Mr Stacy Marks, have been scattered broadcast by advertisers. The purchase of Sir John Millais' picture "Bubbles" for £2200 by the proprietors of a well-known brand of soap, is probably the most remarkable instance of the expenditure in this direction which an advertiser may find profitable. There are in London alone more than 350 advertising agents, of whom upwards of a hundred are known as men in a considerable way of business. The statements which from time to time find currency in the newspapers with regard to the total amount of money annually spent upon advertising in Great Britain and in the United States are necessarily no better than conjectures, but no

detailed statistics are required in order to demonstrate what every reader can plainly see for himself, that advertising has definitely assumed its position as a serious field of commercial enterprise.

Advertising, as practised at the beginning of the 20th century, may be divided into three general classes:—

1. Advertising in periodical publications.
2. Advertising by posters, sign-boards (other than those placed upon premises where the advertised business is conducted), transparencies, and similar devices.
3. Circulars, sent in quantities to specific classes of persons to whom the advertiser specially desired to address himself.

It may be noted at the outset that advertising in periodical publications exercises a reflex influence upon these publications. The daily, weekly, and monthly publications of the day are accustomed to look to advertisements for so large a part of their revenue that the purchaser of a periodical publication receives much greater value for his money than he could reasonably expect from the publisher if the aggregate advertising receipts did not constitute a perpetual subsidy to the publisher. It is not to be supposed, however, that the receipts from the sale of a paper cover all its expenses and that the advertising revenue is all clear profit. The average newspaper reader would be amazed if he knew at how great a cost the day's news is laid before him. A dignified journal displays no inclination to cry from the housetops the vastness of its expenditure, but from time to time an accident enables the public to obtain information in this connexion. The evidence taken by a recent Copyright Commission disclosed that the expenditure of the leading English journal upon foreign news alone amounted to more than £50,000 in the course of one year, and that a year not characterized by any great war to swell the ordinary volume of cable despatches.

In the case of daily papers sold at the minimum price, it is not less obvious that the costliness of news service renders advertising revenue indispensable, for although these less important journals spend less money, the price at which they are supplied to the newsagents is very small in proportion to the cost of their production. If, however, this thought be pursued to its logical conclusion, the advertiser must admit that he in turn receives, from those among newspaper readers who purchase his wares, prices sufficiently high to cover the cost of his advertising. So that the reader is in the curious position of directly paying a certain price for his newspaper, receiving a newspaper fairly worth more than that price, while this price is supplemented by the indirect incidence of a sort of tax upon many of the commodities he consumes. On the other hand, a great part of the advertisements in a daily newspaper have themselves an interest and utility not less than that possessed by the news. The man who desires to hire a house turns to the classified lists which the newspaper publishes day after day, and servants and employers find one another by the same means. The theatrical announcements are so much a part of the news that even if a journal were not paid for their insertion they could not be altogether omitted without inconvenience to the reader. In the main, however, it is the advertiser who seeks the reader, not the reader who seeks the advertiser, and the care with which advertisements are prepared, and the certainty with which the success or failure of a trader may be traced to his skill or want of skill as an advertiser show that the proper use of advertising is one of the most indispensable branches of commercial training.

Before discussing in detail the methods of advertising in periodical publications it may be well to complete, for the use of the general reader, a brief survey of the whole

subject by examining the two other classes of advertisement. The most enthusiastic partisan of advertising will admit that posters and similar devices are very generally regarded by the public as sources of annoyance. A bold headline or a conspicuous illustration in a newspaper advertisement may for a moment force itself upon the reader's attention. In the French, and in some English newspapers, where an advertisement is often given the form of an item of news, the reader is distressed by the constant fear of being hoodwinked. He begins to read an account of a street accident, and finds at the end of the paragraph a puff of a panacea for bruises. The best English and American journals have refused to lend themselves to this sort of trickery, and in no one of the best journals printed in the English language will there be found an advertisement which is not so plainly differentiated from news matter that the reader may avoid it if he sees fit to do so. On the whole, then, newspaper advertisements ask, but do not compel attention. The whole theory of poster advertising is, on the other hand, one of tyranny. The advertiser who pays for space upon a hoarding or wall, although he may encourage a form of art, deliberately violates the wayfarer's mind. A trade-mark or a catch-word presents itself when eye and thought are occupied with other subjects. Those who object to this class of advertisement assert, with some show of reason, that an advertisement has no more right to assault the eye in this fashion than to storm the ear by an inordinate din; and a man who came up behind another man in the street, placed his mouth close to the other's ear, and bawled a recommendation of some brand of soap or tobacco, would be regarded as an intolerable disturber of public peace and comfort. Yet if the owner of a house sees fit to paint advertisements upon his walls, his exercise of the jealously guarded rights of private property may not lightly be disturbed. For the most part, both law and public opinion content themselves with restraining the worst excesses of the advertiser, leaving many sensitive persons to suffer. The National Society for Checking the Abuses of Public Advertising, founded in 1893 in London, was organized for purposes which it describes as follows:—

The society aims at protecting the picturesque simplicity of rural and river scenery, and promoting a regard for dignity and propriety of aspect in towns—with especial reference to the abuses of spectacular advertising.

It seeks to procure legislation whereby local representative bodies would be enabled to exercise control, by means of bye-laws framed with a view to enabling them, at any rate, to grant relief in cases of flagrant and acknowledged abuse.

It is believed that, when regulation is applied in cases where local conditions are peculiarly favourable, the advantage will be so apparent that, by force of imitation and competition, the enforcement of a reasonable standard will gradually become common. The degree of restraint will, of course, depend upon the varying requirements of different places and positions. No hard and fast rule is suggested; no particular class of advertisement is proscribed; certainly no general prohibition of posters on temporary hoardings is contemplated. Within the metropolitan area sky signs have already been prohibited, and it is hoped that some corresponding check will be placed on the multiplication of the field boards which so materially diminish the pleasure or comfort of railway journeys.

The society regards with favour the imposition of a moderate tax or duty for imperial or local purposes on exposed advertisements not coming within certain categories of obviously necessary notices. The difficulty of inducing a Chancellor of the Exchequer to move in a matter where revenue is not the primary consideration is not overlooked. But it is thought that any impost would materially reduce the volume of exposed advertisements, and would at once extinguish the most offensive and the most annoying class, *i.e.*, the quack advertisements by the road sides and the bills stuck by unauthorized persons on trees, walls, and palings.

Members are recommended to make it known that there exists an active repugnance to the present practice of advertising

Poster and sign advertisements.

disfigurement, by giving preference, in private transactions, to makers and dealers who do not employ objectionable methods, and by avoiding, as far as possible, the purchase of wares which, in their individual opinion, are offensively puffed. Action on these lines is advised rather for its educational than for its immediately deterrent effect; although, in the case of many of the more expensive commodities, makers would undoubtedly be much influenced by the knowledge that they would lose, rather than gain, custom.

The foregoing proposals are based on the following estimate of the conditions of the problem. It is believed that the present licence causes discomfort or loss of enjoyment to many, and that, in the absence of authoritative restriction, it must grow far beyond its present limits; that beauty or propriety of aspect in town and country form as real a part of the national wealth as any material product, and that to save these from impairment is a national interest; that the recent developments of vexatiously obtrusive advertising have not grown out of any necessities of honourable business, but are partly the result of a mere instinct of imitation, and partly are a morbid phase of competition by which both the consumers and the trade as a whole lose; that restriction as regards the size and positions of advertising notices would not be a hardship to those who want publicity—since all competitors would be treated alike, each would have the same relative prominence; that, as large sums of public money are expended on institutions intended to develop the finer taste, and on edifices of elaborate design, it must be held inconsistent with established public policy to permit the sensibilities thus imparted to be wounded, and architectural effect to be destroyed at the discretion of a limited class.

The influence of this society is to be seen in many of the restrictions which have been imposed upon advertisers since its work began. About a year after its foundation the London County Council abolished (under statutory powers obtained from Parliament) advertisements coming within the definition of sky-signs in the London Building Act of 1894. These specifications are as follows:—

“Sky sign” means any word, letter, model, sign, device, or representation in the nature of an advertisement, announcement, or direction supported on or attached to any post, pole, standard, framework, or other support, wholly or in part upon, over, or above any building or structure, which, or any part of which, sky sign shall be visible against the sky from any point in any street or public way, and includes all and every part of any such post, pole, standard, framework, or other support. The expression “sky sign” shall also include any balloon, parachute, or similar device employed wholly or in part for the purposes of any advertisements or announcement on, over, or above any building, structure, or erection of any kind, or on or over any street or public way.

The Act proceeds to exclude from its restrictions flag-staffs, weathercocks, and any solid signs not rising more than 3 feet above the roof.

Another bye-law of the London County Council, in great measure due to the observations made at coroners’ inquests, protects the public against the annoyances and the perils to traffic occasioned by flashlight and searchlight advertisements. This bye-law reads as follows:—

No person shall exhibit any flashlight so as to be visible from any street and to cause danger to the traffic therein, nor shall any owner or occupier of premises permit or suffer any flashlight to be so exhibited on such premises.

The expression “flashlight” means and includes any light used for the purpose of illuminating, lighting, or exhibiting any word, letter, model, sign, device, or representation in the nature of an advertisement, announcement, or direction which alters suddenly either in intensity, colour, or direction.

No person shall exhibit any searchlight so as to be visible from any street and to cause danger to the traffic therein, nor shall any owner or occupier of premises permit or suffer any searchlight to be so exhibited on such premises.

The expression “searchlight” means and includes any light exceeding 500-candle power, whether in one lamp or lantern, or in a series of lamps or lanterns used together and projected as one concentrated light, and which alters either in intensity, colour, or direction.

Advertising vans were so troublesome in London as to be prohibited in 1853; the “sandwich-man” has in the City of London and many towns been ousted from the pavement to the gutter, from the more crowded to the

less crowded streets, and as the traffic problem in the great centres of population becomes more urgent, he will probably be altogether suppressed.

Hoardings are now so restricted by the London Building Acts that new hoardings cannot, except under special conditions, be erected exceeding 12 feet in height, and no existing hoardings can be increased in height so as to exceed that limit.

The huge signs which some advertisers, both in England and the United States, have placed in such positions as to mar the landscape, have so far aroused public antagonism that there is reason to hope that this form of nuisance will not increase.

In 1899 Edinburgh obtained effective powers of control over all sorts of advertising in public places, and this achievement has been followed by no little agitation in favour of a Parliamentary enactment which should once for all do away with the defacing of the landscape in any part of the United Kingdom. The society already mentioned has drafted a Rural Advertisements Bill in the following terms:—

(1) The power of a County Council to make bye-laws conferred by Section 16 of the Local Government Act 1888, shall, subject to the provisions of that section, extend to bye-laws:—

(a) For regulating or prohibiting the erection or placing of advertisements in or upon any arable or pasture land, woodland, garden, public park, common, or waste land, foreshore, or any inland or tidal water.

(b) For enforcing the removal of advertisements erected or placed in contravention of the bye-laws.

(c) For enforcing the removal, within a prescribed time—not being less than one year after the bye-laws come into operation—of any advertisements erected or placed before the making of the bye-laws in such a manner as would be in contravention of the bye-laws, if the same had been previously made.

(2) Nothing in any bye-law to be made under this Act shall affect any advertisement erected or placed either before or after the passing of this Act, upon any premises and relating solely to any trade, business, or business transaction carried on, or proposed to be carried on, or any entertainment or meeting held or to be held, upon or in relation to the said premises or to any property thereon.

(3) This Act shall not apply to or have any effect in the administrative county of London or in any [municipal] borough.

The English law with regard to posters has undergone very little change. The Metropolitan Police Act 1839 (2 & 3 Vict. cap. 47) first put a stop to unauthorized posting, and the Indecent Advertisements Act of 1889 (section 3) penalized the public exposure of any picture or printed or written matter of an indecent or obscene nature. But in general practice there is hardly any limitation to the size or character of poster advertisements, other than good taste and public opinion. On the other hand, public opinion is a somewhat vague entity, and there have been cases in which a conflict has arisen as to what public opinion really was, when its legally authorized exponent was in a position to insist on its own arbitrary definition. Such an instance occurred some few years ago in the case of a large poster issued by a well-known London music-hall. The Progressive majority on the London County Council, led by Mr M'Dougall, a well-known “purity” advocate, took exception to this poster, which represented a female gymnast in “tights” posed in what was doubtless intended for an alluring and attractive attitude; and, in spite of any argument, the fact remained that the decision as to renewing the license of this music-hall rested solely with the Council. In showing that it would have no hesitation in provoking even a charge of meddling prudery, the Council probably gave a salutary warning to people who were inclined to sail rather too near the wind. But in Great Britain and America, at all events (though a doubt may perhaps exist as to some Continental countries), the advertiser and the artist are restrained, not only by their

own sense of propriety, but by fear of offending the sense of propriety in their customers.

Posters and placards in railway stations and upon public vehicles still embarrass the traveller who desires to find the name of a station or the destination of a vehicle. In respect of all these abuses it is a regrettable fact that unpopularity cannot be expected to deter the advertiser. If a name has once been fixed in the memory, it remains there long after the method of its impression has been forgotten, and the purpose of advertisements of the class under discussion is really no more than the fixing of a trade name in the mind. The average man or woman who goes into a shop to buy soap is more or less affected by a vague sense of antagonism toward the seller. There is a rudimentary feeling that even the most ordinary transaction of purchase brings into contact two minds actuated by diametrically opposed interests. The purchaser, who is not asking for a soap he has used before, has some hazy suspicion that the shopkeeper will try to sell, not the article best worth the price, but the article which leaves the largest margin of profit; and the purchaser imagines that he in some measure secures himself against a bad bargain when he exercises his authority by asking for some specific brand or make of the commodity he seeks. If he has seen any one soap so persistently advertised that his memory retains its name, he will ask for it, not because he has any reason to believe it to be better or cheaper than others, but simply because he baffles the shopkeeper, and assumes an authoritative attitude by exerting his own freedom of choice. This curious and obscure principle of action probably lies at the root of all poster advertising, for the poster does not set forth an argument as does the newspaper advertisement. It hardly attempts to reason with the reader, but merely impresses a name upon his memory. It is possible, by lavish advertising, to go so far in this direction that the trade-mark of a certain manufacturer becomes synonymous with the name of a commodity, so that when the consumer thinks of soap or asks for soap, his concept inevitably couples the maker's name with the word "soap" itself. In order that the poster may leave any impression upon his mind, it must of course first attract his attention. The assistance which the advertiser receives from the artist in this connexion is discussed in the article POSTERS.

The fact that the verb "to circularize" was first used in 1848, sufficiently indicates the very recent origin of the practice of plying possible purchasers with printed letters and pamphlets. The penny postage was not established in England until 1840; the halfpenny post for circulars was not introduced until 1855. In the United States a uniform rate of postage at two cents was not established until 1833. In both countries cheap postage and cheap printing have so greatly encouraged the use of circulars that the sort of people whom the advertiser desires to reach—those who have the most money to spend, and whose addresses, published in directories, indicate their prosperous condition—are overwhelmed by tradesmen's price-lists, appeals from charitable institutions, and other suggestions for the spending of money. The addressing of envelopes and enclosing of circulars is now a recognized industry in many large towns both in Great Britain and in the United States. It seems, however, to be the opinion of expert advertisers that what is called "general circularizing" is unprofitable, and that circulars should only be sent to persons who have peculiar reason to be interested by their specific subject-matter. It may be noted, as an instance of the assiduity with which specialized circularizing is pursued, that the announcement of a birth, marriage, or

death in the newspapers serves to call forth a grotesque variety of circulars supposed to be adapted to the momentary needs of the recipient.

In concluding this review of methods of advertising, other than advertisements in periodical publications, we may add that the most extraordinary attempt at advertisement which is known to exist is to be found at the churchyard at Godalming, Surrey, where the following epitaph was placed upon a tombstone:—

Sacred
To the memory of
Nathaniel Godbold Esq.
Inventor & Proprietor
of that excellent medicine
The Vegetable Balsam
For the Cure of Consumptions & Asthmas.
He departed this Life
The 17th. day of Decr. 1799
Aged 69 years.
Hic Cineres, ubique Fama.

The preparation of advertisements for the periodical press has within the last twenty years or so become so important a task that a great number of writers and artists—many of the latter possessing considerable abilities—gain a livelihood from this pursuit. The ingenuity displayed in modern newspaper advertising is unquestionably due to American initiative. The English newspaper advertisement of twenty years ago consisted for the most part of the mere reiteration of a name. An advertiser who took a column's space, supplied enough matter to fill an inch, and ingenuously repeated his statement throughout the column. Such departures from this childlike method as were made were for the most part eccentric to the point of incoherence. It may, however, be said in defence of English advertisers, that newspaper publishers for a long time sternly discountenanced any attempt to render advertisements attractive. So long as an advertiser was rigidly confined to the ordinary single-column measure, and so long as he was forbidden to use anything but the smallest sort of type, there was very little opportunity for him to attract the reader's attention. The newspaper publisher must always remember that the public buy a newspaper for the sake of the news, not for the sake of the advertisements, and that if the advertisements are relegated to a position and a scope, in respect of display, so inferior that they may be overlooked, the advertiser cannot afford to bear his share of the cost of publication. Of late *The Times*, followed by almost all newspapers in the United Kingdom, has given the advertiser as great a degree of liberty as he really needs, and many experienced advertisers in America incline to the belief that the larger license accorded to American advertisers defeats its own ends. The truth would seem to be that the advertiser will always demand, and may fairly expect, the right to make his space as fantastic in appearance as that allotted to the editor. When some American editors see fit to print a headline in letters as large as a man's hand, and to begin half-a-dozen different articles on the first page of a newspaper, continuing one on page 2, another on page 4, and another on page 6, to the bewilderment of the reader, it can hardly be expected that the American advertiser should submit to any very strict code of decorum. The subject of the relation between a newspaper proprietor and his advertisers cannot be dismissed without reference to the notable independence of advertisers' influence, which English and American newspaper proprietors authorize their editors to display. Whenever an insurance company or a bank goes wrong, the cry is raised that all the editors in Christendom had known for years that the directors were imbeciles and rogues, but had conspired to

Advertis-
ing in
periodical
publica-
tions.

keep mute for the sake of an occasional advertisement. When the British public persisted, not long ago, in paying premium prices for the shares of over-capitalized companies, the crash had no sooner come than the newspapers were accused of having puffed promotions for the sake of the money received for publishing prospectuses. As a matter of fact, in the case of the best dailies in England and America, the editor does not stand at all in awe of the advertiser, and time after time the Money Article has ruthlessly attacked a promotion of which the prospectus appeared in the very same issue. It is indeed to the interest of the advertiser, as well as to the interest of the reader, that this independence should be preserved, for the worth of any journal as an advertising medium depends upon its possessing a *bond-fide* circulation among persons who believe it to be a serious and honestly-conducted newspaper. All advertisers know that the minor weeklies, which contain nothing but trade puffs, and are scattered broadcast among people who pay nothing for their copies, are absolutely worthless from the advertiser's point of view. The most striking difference between the periodical press of Great Britain and that of America is, that in the former country the magazines and reviews play but a secondary rôle, while in the United States the three or four monthlies possessing the largest circulation are of the very first importance as advertising mediums. One reason for this is that the advertisements in an American magazine are printed on as good paper, and printed with as great care, as any other part of the contents. There are probably very few among American magazine readers who do not habitually look through the advertising pages, with the certainty that they will be entertained by the beauty of the advertiser's illustrations and the quaint curtness of his phrases. Another reason is that the American monthly magazine goes to all parts of the United States, while, owing to the time required for long journeys on even the swiftest trains, no American daily paper can have so general a circulation as *The Times* in the United Kingdom. In comparison with points on the Pacific coast, Chicago does not seem far from New York, yet, with the exception of one frenzied and altogether unsuccessful attempt, no New York daily has ever attempted to force a circulation in Chicago. The American advertiser would, therefore, have to spend money on a great number of daily papers in order to reach as widespread a public as one successful magazine offers him.

There is reason to believe that the English magazine publishers have erred gravely in taking what are known in the trade as "insets," consisting of separate cards or sheets printed at the advertiser's cost, and accepted by the publisher at a specific charge for every thousand copies. This system of insetting has the grave inconvenience that the advertiser finds himself compelled to print as many insets as the publisher asserts that he can use. The publisher, on the other hand, is somewhat at the mercy of too enthusiastic agents and employes, who estimate over-confidently the edition of the periodical which will probably be printed for a certain month, and advertisers have had reason to fear that many of their insets were wasted. The added weight and bulk of the insets cause inconvenience and expense to the newsdealer, as two or three insets printed upon cardboard are equivalent to at least sixteen additional pages. Some newsdealers have further complicated the inset question by threatening to remove insets unless special tribute be paid to them; and with all these difficulties to be considered, many magazine publishers have seriously considered the advisability of altogether discontinuing the practice of taking insets, and of confining their advertisements to the sheets they themselves print. In connexion with this subject, it may be added that many readers habit-

ually shake loose bills out of a magazine before they begin to turn the pages, and that railway stations, railway carriages, and even public streets, are thus littered with trampled and muddy advertisements. The old practice of distributing handbills in the streets is dying a natural death, more or less hastened by local bye-laws, and when the loose bills in magazines and cheap novels have ceased to exist no one will be the loser.

Advertisements in the weekly press are on the whole more successful in England than in America. A few American weeklies cope successfully with the increasing competition of the huge Sunday editions of American daily papers. But even the most successful among them—a paper for boys—has hardly attained the prosperity of some among its English contemporaries in the field of weekly journalism.

The merchant who turns to these pages for practical suggestions concerning the advertising of his own business, can be given no better advice than to betake himself to an established advertising agent of good repute, and be guided by his counsels. The chief part that he can himself play with advantage is to note from day to day whether the agent is obtaining advantageous positions for his announcements. Every advertiser will naturally prefer a right-hand page to a left-hand page, and the right side of the page to the left side of the page; while the advertiser who most indefatigably urges his claims upon the agent will, in the long run, obtain the largest share of the favours to be distributed. To the merchant who inclines to consider advertising in connexion with the broader aspects of his calling, it may be suggested that a new channel of trade demands very serious attention. What is called in England "postal trade," and in America "mail order business," is growing very rapidly. Small dealers in both countries have complained very bitterly of the competition they suffer from the general dealers and from stores made up of departments which, under one roof, offer to the consumer every imaginable sort of merchandise. This general trading, which, on the one hand, seriously threatens the small trader, and on the other hand offers greater possibilities of profit to the proportionately small number of persons who can undertake business on so large a scale, becomes infinitely more formidable when the general dealer endeavours not only to attract the trade of a town, but to make his place of business a centre from which he distributes by post his goods to remote parts of the country. In America, where the weight of parcels carried by post is limited to four pounds, and where the private carrying companies are forced to charge a very much higher rate for carriage from New York to California than for shorter distances, the centralization of trade is necessarily limited; but it is no secret that, at the present moment, persons residing in those parts of the United Kingdom most remote from London habitually avail themselves of the English parcel post, which carries packages up to eleven pounds, in order to procure a great part of their household supplies direct from general dealers in London. A trading company, which conducts its operations upon such a scale as this, can afford to spend an almost unlimited sum in advertising throughout the United Kingdom, and even the trader who offers only one specific class of merchandise is beginning to recognize the possibility of appealing to the whole country.

With regard to the literature of advertising, it need only be added that, in addition to the historical article in the *Edinburgh Review* for February 1843, already mentioned, and that in the *Quarterly Review* for June 1855, the advertisers' handbooks, issued by the leading advertising agents, will be found to contain practical information of great use to the advertiser.

Adye, Sir John Miller (1819-1900), British general and colonel commandant royal artillery, son of Major James P. Adye, royal artillery, was born at Sevenoaks, Kent, on the 1st of November 1819. He entered the royal artillery in 1836, was promoted captain in 1846, and served throughout the Crimean War of 1854-56, as brigade-major and assistant adjutant-general of artillery (medal with four clasps, Turkish medal, third class of the Legion of Honour, fourth class of the Medjidie, C.B., and brevets of major and lieutenant-colonel). In the Indian Mutiny he served on the staff in a similar capacity (medal). Promoted brevet-colonel in 1860, he was specially employed in 1863 in the N.W. frontier of India campaign (medal with clasp), and was deputy adjutant-general, Bengal, from 1863 to 1866, when he returned home. From 1870 to 1875 Adye was director of artillery and stores at the War Office, where his influence was used to prevent the introduction of breech-loading ordnance. He was made a K.C.B. in 1873, having taken an active part in Mr Cardwell's army reform. He was promoted to be major-general and appointed governor of the Royal Military Academy at Woolwich in 1875, and surveyor-general of the ordnance in 1880. In 1882 he was chief of the staff and second in command of the expedition to Egypt, and served throughout the campaign (medal with clasp, bronze star, second class of the Medjidie, G.C.B., and thanks of Parliament). He held the government of Gibraltar from 1883 to 1886. Promoted lieutenant-general in 1879, and general and colonel commandant of royal artillery in 1884, he retired in 1886. He unsuccessfully contested the Parliamentary representation of Bath in the Liberal interest in 1892. He died on 26th August 1900, when on a visit to Lord Armstrong in Northumberland. He was the author of *A Review of the Crimean War*; *The Defence of Cawnpore*; *A Frontier Campaign in Afghanistan*; *Recollections of a Military Life*; and *Indian Frontier Policy*.

(R. H. V.)

Egades, or **ÆGATES**, in Italian *Egadi*, a group of islands lying W. of Sicily and belonging to the prov. of Trapani, the largest being Marittimo, the ancient *Hiera*, rising to 2244 feet in Mount Falcone; Levanzo, the ancient *Phorbantia*, rising to 951 feet; and Favignana, the ancient *Ægusa*; altitude, 1070 feet; area of all, 70 square miles. Total population (1901), 6419. They carry on tunny and sponge fishing. Marittimo has a state prison, and produces honey and capers. Chief town and port, Favignana; cleared annually by some 400 vessels of about 100,000 tons. Population (1901), 5001.

Aeltre, a town of Belgium, in the province of East Flanders, 12 miles W. by N. of Ghent by rail, near the Ghent and Bruges canal. Its trade is mainly in linen and wood. Population (1900), 6261; communal (1880), 7020; (1897), 7174.

Aeronautics.—Notwithstanding the prejudice consequent on past failures and upon premature assertion of impending success, the advance in aeronautics since the publication of the ninth edition of this work has been greater and more rapid than at any time in history. This advance has consisted in:—(1) The evolution of light motors; (2) the elucidation of natural laws; (3) many partially successful experiments. Electric, steam, gas, or petroleum engines have been reduced to a fraction of their former weights, formerly-accepted data for computations have been quite superseded, and numerous experiments have been made.

Few scientific men have imitated Mr Glaisher in making high ascents for meteorological observations.

Balloons. Sivel, Crocé-Spinelli, and Tissandier, who reached 27,950 feet on 15th April 1875, were asphyxiated,

and only Tissandier came down alive. This put a stop to such attempts for a time; but Gross and Berson attained 25,840 feet on 11th May 1894, Berson reached 29,740 feet on 4th December 1894, recording a temperature of -54° F., and Berson and Spencer are stated by the latter to have attained 27,500 feet on 15th September 1898, the thermometer registering -29° F. The personal danger attending such ascents led Hermite and Besançon to inaugurate in November 1892 the sending up of unmounted balloons (Ballons Sondes), equipped with automatic recording instruments (see METEOROLOGY): On 11th July 1897, Andrée, Strindberg, and Fränkel ascended from Spitzbergen in a daring attempt to reach the North Pole by balloon. One carrier pigeon, apparently liberated forty-eight hours after the start, was shot, and two floating buoys with messages were found; but nothing more has been heard of the explorers.

From the very first invention of balloons the problem has been how to navigate them by propulsion. General Meusnier proposed an elongated balloon in 1784. It was experimented on by Robert Brothers, who made two ascensions and claimed to have obtained a deviation of 22° from the direction of a light wind by means of aerial oars worked by hand. The relative speed was probably about 3 miles an hour, and it was so evident that a very much more energetic light motor than any then known was required to stem ordinary winds that nothing more was attempted till 1852, when Giffard ascended with a steam-engine of then unprecedented lightness. The subjoined table exhibits the subsequent progress which has been made:—

Experiments with Dirigible Balloons.

Year.	Inventor.	Length.	Diameter.	Contents.	Lifting Capacity.	Weight of Balloon.	Weight of Motor.	H.-P.	Speed per hour.
1852	Giffard	144	39	88,800	3,378	2,794	462	8.0	6.71
1872	De Lôme	118	49	120,088	8,358	4,728	2000	0.8	6.26
1884	Tissandier	92	30	37,439	2,728	933	616	1.5	7.82
1885	Renard and Krebs	165	27	65,886	4,402	2,449	1174	9.0	14.00
1897	Wölfert	92	28	8.0	..
1897	Schwarz	157	{ 46 } { 39 }	180,500	8,188	6,800	800?	16.0	17.00
1900	Zeppelin	420	39	400,000	25,000	19,000	1500	32.0	18.00

Giffard, the future inventor of the injector, devised a steam-engine weighing, with fuel and water for one hour, 154 lb per horse-power, and was bold enough to employ it in proximity to a balloon inflated with coal gas. He was not able to stem a medium wind, but attained some deviation. He repeated the experiment in 1855 with a more elongated spindle, which proved unstable and dangerous. During the siege of Paris the Government decided to build a navigable balloon, and entrusted the work to the chief naval constructor, Dupuy de Lôme. He went into the subject very carefully, made estimates of all the strains, resistances, and speeds, and tested the balloon in 1872. Deviations of 12° were obtained from the course of a wind blowing 27 to 37 miles per hour. The screw propeller was driven by eight labourers, a steam-engine being deemed too dangerous; but it was estimated that had one been used, weighing as much as the men, the speed would have been doubled. Tissandier and his brother applied an electric motor, lighter than any previously built, to a spindle-shaped balloon, and went up twice in 1883 and 1884. On the latter occasion he stemmed a wind of 7 miles per hour. The brothers abandoned these experiments, which had been carried on at their own expense, when the French War Department took up the problem. Renard and Krebs, the officers in charge of the War Aeronautical Department at Meudon, built and experimented with in 1884 and 1885 the fusiform balloon "La France," in which the "master" or maximum section was about one-quarter of the distance from the stem. The propelling screw was at the front of the car and driven by an electric motor of unprecedented lightness. Seven ascents were made on very calm days, a maximum speed of 14 miles an hour was obtained, and the balloon returned to its starting-point on five of the seven occasions. Since then another balloon has been constructed, said to be capable of a speed of 22 to 28 miles per hour, with a different motor; but no tests are known to the public and the secrets of this war engine

are carefully guarded. After many years of experiment Dr Wölfert built and experimented with in Berlin, in 1897, a cigar-shaped balloon driven by a gasoline motor. An explosion took place in the air, the balloon fell, and Dr Wölfert and his assistant were killed. It was also in 1897 that an aluminium balloon was built from the designs of D. Schwarz (then deceased) and tested in Berlin. It was driven by a Daimler benzine motor, and attained a greater speed than "La France"; but a driving belt slipped off its pulley, and in coming down the balloon was injured beyond repair. From 1897 to 1900 Count Zeppelin, of the German army, was engaged in constructing an immense balloon, truly an air ship, of most careful and most intelligent design, to carry five men. It was first tested in June 1900, when it attained a speed of 18 miles an hour and travelled a distance of 3½ miles before an accident to the steering gear necessitated the discontinuance of the experiment. In 1901 M. Santos Dumont carried out some more or less successful experiments with a dirigible balloon in Paris.

The principles which govern the design of the dirigible balloon may be said to have been evolved. As the lifting power grows as the cube of the dimensions, and the resistance approximately as the square, the advantage lies with the larger sizes of balloons, as of ocean steamers, up to the limits within which they may be found practicable. Count Zeppelin may have reached the limit as to practicable size. He has gained an advantage by attaching his propellers to the balloon, instead of to the car as heretofore; but this requires a rigid framework and a great increase of weight. Le Compagnon endeavoured, in 1892, to substitute flapping wings for rotary propellers, as the former can be suspended nearer the centre of resistance. Danilewsky followed him in 1898 and 1899, but thus far without remarkable results. Dupuy de Lôme was the first to estimate in detail the resistances to balloon propulsion, but experiment showed that in the aggregate they were greater than he calculated. Renard and Krebs also found that their computed resistances were largely exceeded, and after revising the results they gave the formula $R=0.01685 D^2V^2$, R being the resistance in kilograms, D the diameter in metres, and V the velocity in metres per second. Reduced to British measures, in pounds, feet, and miles per hour, $R=0.0006876 D^2V^2$, which is somewhat in excess of the formula computed by Dr Pole from De Lôme's experiments. The above coefficient applies only to the shape and rigging of the balloon "La France," and combines all resistances into one equivalent, which is equal to that of a flat plane 18 per cent. of the "master section." This coefficient may perhaps hereafter be reduced by one-half through a better form of hull and car, more like a fish than a spindle, by diminished sections of suspension lines and net, and by placing the propeller at the centre of resistance. To compute the results to be expected from new projects, it will be preferable to estimate the resistances in detail. The following table shows how this was done by De Lôme, and the probable corrections which should have been made by him:—

Resistances—De Lôme's Balloon.

Computed by De Lôme. V = 2.22 m. per sec.					More Probable Values. V = 2.82 m. per sec.		
Part.	Area, Sq. Metre.	Coefficient.	Air Pressure.	Resistance, Kg.	Coefficient.	Air Pressure.	Resistance, Kg.
Hull, without net.	172.96	1/30	0.665	3.830	1/15	0.875	10.091
Car	3.25	1/5	"	0.432	1/5	"	0.569

Large cords	9.90	1/3	"	2.194	1/3	"	2.887
				11.031			21.984

When the resistances have been reduced to the lowest possible minimum by careful design, the attainable speed will depend upon the efficiency of the propeller and the relative lightness of the motor. It seems not unlikely that 30 miles per hour can be attained in the near future, but the commercial uses will be small, as the balloons must remain housed when the wind aloft is brisk. The sizes will be great and costly, the loads small, and the craft frail and short-lived, yet dirigible balloons constitute the proper type for Governments to evolve, until they are superseded by efficient flying machines.

While the flying machine is still inferior to the balloon in performance and safety, it has made more progress since 1888 than during the preceding three centuries. Investigation has turned from flapping wings and *Flying machines.* from sustaining screws to the aeroplane type, and encouraging results have been obtained not only with models but with full-sized machines. The flights have been very short and hazardous, but the speeds have been much greater than with balloons. The danger involved in the proximity of fire to gas being absent, Maxim, Langley, Ader, and others have produced steam motors weighing 10 lb or less per horse-power. This, it is true, is exclusive of fuel and water, and the engines work nearly to the limits of endurance; but the automobile industry is developing gasoline motors which are nearly as light, and these may prove better adapted to aerial propulsion. Knowledge has been greatly increased as to the laws of flight. Professor Marey has furnished new data concerning bird locomotion, and Professor Langley has elucidated the problem of air reactions on oblique planes. Physicists still computed, down to 1891, the normal pressures upon oblique planes as varying in the ratio of the square of the sine of the angle of incidence or, at best, in the ratio of the sine of that angle. Langley showed, by extensive experiments, that this normal had nearly twice the assigned value, and that Duchemin's empirical formula

$$N = P \frac{2\sin \alpha}{1 + \sin^2 \alpha}$$

which was proposed about 1838 but not adopted, was approximately correct for oblique planes. More than this, Lilienthal showed, about the same time, that concave bird-like surfaces afforded from three to seven times as much support as planes at acute angles of incidence, and gave also a small propelling component, so that former views and modes of calculating the surfaces and power required for

flight have been quite revolutionized. Experiments have therefore been more intelligent and more successful than

1 The pounds sustained per horse-power in the last three experiments will probably be reduced one-half when an artificial motor is substituted for gravity.

ever before. It can no longer be said that men have never flown through the air. The preceding table (p. 101) but this was still very good. The equilibrium was defective and greatly shortened the possible flights. A score of different models have been produced by Hargrave, of New South Wales, since 1885. His No. 16 has been selected for the table given. It consisted in a body plane of kite shape, propelled by a pair of flapping vanes at the front (Figs. 1, 2, 3). Hargrave built a number of steam-engines weighing about 10 lb per h.p., but found such difficulties that he turned his attention to oil motors. He advocates large surfaces and low speeds, and hopes to maintain those proportions by suspending a motor and propellers from a

exhibits the more important performances, and attention is called to the columns of pounds imposed per square

FIG. 2.—Engine for Hargrave's flying machine. (From *Engineering*.)

foot, to the resulting speed required for support, and to the pounds sustained per horse-power (the apparatus marked thus * carried a man or men).

The first aeroplane of Tatin (1879) consisted of a pair of flat wings and a tail, traction being obtained from two screw propellers at the front. The horse-power was arrived at by allowing 25 to 30 per cent. of that shown by the indicator for the compressed air. When Tatin and Richet substituted steam in 1897 they only sustained about half as many pounds per h.p. ;

tandem team of the "Cellular Kites" which he has invented, and with which he has been lifted from the ground. The apparatus of Phillips resembles a Venetian blind. The slats are of wood, convex on the upper surface and concave beneath. The lift is apparently very good, but the stability is defective. After many preliminary experiments on air reactions, Maxim tested, in 1894, a very large flying machine, a marvel of ingenuity and mechanical skill, carrying three men. It consisted in a combination of superimposed aeroplanes, driven by two screw propellers, which were rotated by a compound steam-engine of 363 h.p., weighing with its adjuncts some 10 lb per h.p. The apparatus gathered speed on a railway track, and demonstrated that it could lift much more than its own weight; but the pounds sustained per h.p. were less than was expected, probably by reason of head resistance caused by many guy wires, and the stability was inadequate. After publishing his *Experiments in Aerodynamics* in 1891, Langley produced in 1896 a steam-driven flying model, with which he obtained the longest flights

FIG. 3.—Another type of engine for Hargrave's flying machine. (From *Engineering*.)

ever known. The apparatus consisted of two pairs of wings and a tail, with two screw propellers, driven by a high pressure steam-engine of 1 h.p. weighing but 7 lb. The longest flight was over $\frac{3}{4}$ of a mile, and the apparatus alighted safely on each of the three flights made. The lift per horse-power was low, for a variety of reasons, but the stability was good. After having tested, in 1872 and in 1891, two full-sized flying machines, producing indifferent results, Ader built, in 1897, a third apparatus with funds furnished by the French Government. This reproduced the structure of a bird with almost servile imitation, save that traction was obtained by two screw pro-

pellers (Figs. 4, 5). The steam-engines weighed about 7 lb per h.p., but the equilibrium of the apparatus was defective. To Lilienthal belongs the double credit of demonstrating the superiority of arched surfaces over planes, and of reducing gliding flight to regular practice. He made over 2000 glides safely, using gravity as a motive-power, with various forms of apparatus, consisting of concave bat-like wings, in some cases superimposed. It

their propellers, shafting, supplies, &c., weighing less than 20 lb per h.p. The problem, then, is how they should be designed. The knowledge evolved within the last few years has at last made it practicable to give some data for calculating the effects to be expected, with some confidence that they will not be far wrong. It is evident that an apparatus must be designed to be as light as possible, and also to reduce to a minimum all resistances to propulsion. This being kept in view, the strength and consequent section required for each member may be calculated by the methods employed in proportioning bridges, with the difference that the support (from air pressure) will be considered as uniformly distributed, and the load as concentrated at one or more points. Smaller factors of safety may also have to be used. Knowing the sections required and unit weights of the materials to be employed, the

weight of each part can be computed. If a model has been made to absolutely exact scale, the weight of the full-sized apparatus may approximately be ascertained by the formula

$$W' = W \sqrt{\left(\frac{S'}{S}\right)^3},$$

in which W is the weight of the model, S its surface, and W' and S' the weight and surface of the intended apparatus. Thus if the model has been made one-quarter size in its homologous dimensions, the supporting surfaces will be sixteen times, and the total weight sixty-four times, those of the model. The weight and the surface being determined, the three most important things to know are the angle of incidence, the "lift," and the

was with a machine of the latter type that he was upset by a sudden gust of wind and killed in 1896. Pilcher improved somewhat upon Lilienthal's apparatus, but used the same general method of restoring the balance, when endangered, by shifting the weight of the operator's body. He made several hundred glides in safety, until he too was upset by a gust of wind and killed in 1899. Chanute confined his endeavours exclusively to the evolution of automatic stability, and made the surfaces movable instead of the man. He obtained over 1000 glides without accident with two different types of apparatus. The last three experimenters have claimed that it is not impossible for man to imitate the soaring flight of certain birds, wherein support and propulsion are obtained from the wind alone under certain favourable conditions.

The very first essential for success is safety, which will probably only be attained with automatic stability, and the foregoing account indicates that it is for lack of this that all the experiments have shown such slight success. Safety and stability are therefore to be sought first. The underlying principle is that the centre of gravity shall at all times be on the same vertical line as the centre of pressure. The latter varies with the angle of incidence. For square planes it moves approximately, as expressed by Joessel's formula: $C = (0.2 + 0.3 \sin \alpha)L$, in which C is the distance from the front edge, L the length fore and aft, and α the angle of incidence. The movement is different on concave surfaces, but has not been formulated. The term *Aeroplane* is understood to apply to flat sustaining surfaces, but experiment indicates that arched surfaces are more efficient. Langley has proposed the word *Aerodrome*, which seems the preferable term for apparatus with wing-like surfaces. This type is the one which results point to as the proper type for further experiments. With this it seems probable that, with well-designed apparatus, 40 to 50 lb can be sustained per indicated h.p., or about twice that quantity per resistance or "thrust" h.p., and that some 30 or 40 per cent. of the weight can be devoted to the machinery, thus requiring motors, with

required speed. The fundamental formula for rectangular air pressure is well known: $P = KV^2S$, in which P is the rectangular normal pressure, in pounds or kilograms, K a coefficient, (0.0049 for British, and 0.11 for metric measures), V the velocity in miles per hour or in metres per second, and S the surface in square feet or in square metres. The normal on oblique surfaces, at various angles of incidence, is given by the formula $P = KV^2S\eta$, which

FIG. 4.—Ader's "Avion" in position for flight. (From *The Scientific American*.)

FIG. 5.—Ader's "Avion" with the wings folded. (From *The Scientific American*.)

latter factor is given both for planes and for arched surfaces in the subjoined table:—

Percentages of Air Pressure at Various Angles of Incidence.

The sustaining power, or "lift," which in horizontal flight must be equal to the weight, can be calculated by the formula: $L = KV^2 S \eta \cos \alpha$, or the factor may be taken direct from the table, in which the "lift" and the "drift" have been obtained by multiplying the normal η by the cosine and sine of the angle. The last column shows the tangential pressure on concave surfaces which Lilienthal found to possess a propelling component between 3° and 32°, and therefore to be negative to the relative wind. Former modes of computation indicated angles of 10° to 15° as necessary for support with planes. These were prohibitory in consequence of the great "drift"; but the present data indicate that, with concave surfaces, angles of 2° to 5° will produce adequate "lift." To compute the latter the angle at which the wings are to be set must first be assumed, and that of +3° will generally be found preferable. Then the required velocity is next to be computed by the formula:

$$v = \sqrt{\frac{L}{KS \eta \cos \alpha}}$$

or for concave wings at +3°:

$$v = \sqrt{\frac{W}{0.545KS}}$$

Having thus determined the weight, the surface, the angle of incidence, and the required speed for horizontal support, the next step is to calculate the power required. This is best accomplished by first obtaining the total resistances, which consist of the "drift" and of the head resistances due to the hull and framing. The latter are arrived at preferably by making a tabular statement similar to that shown under the head of balloons, showing all the spars and parts offering head resistance, and applying to each the coefficient appropriate to its "master section," as ascertained by experiment. Thus is obtained an "equivalent area" of resistance, which is to be multiplied by the wind pressure due to the speed. Care must

be taken to resolve all the resistances at their proper angle of application, and to subtract or add the tangential force, which consists in the surface S, multiplied by the wind pressure, and by the factor in the table, which is, however, 0 for 3° and 32°, but positive or negative at other angles. When the aggregate resistances are known, the "thrust h.p." required is obtained by multiplying the resistance by the speed, and then allowing for mechanical losses in the motor and propeller, which losses will generally be 50 per cent. of indicated h.p. Close approximations are obtained by the above method when applied to full-sized apparatus. The following example will make the process clearer. The weight to be carried by an apparatus was 189 lb on concave wings of 143.5 sq. ft. area, set at a positive angle of 3°. There were in addition rear wings of 29.5 sq. ft., set at a negative angle of 3°, carrying no weight; hence $L = 189 = 0.005 \times V^2 \times 143.5 \times 0.545$.

Whence $V = \sqrt{\frac{189}{0.005 \times 143.5 \times 0.545}} = 22$ miles per hour, at which the air pressure would be 2.42 lb per sq. ft. The area of spars and man was 17.86 sq. ft., reduced by various coefficients to an "equivalent surface" of 11.70 sq. ft., so that the resistances were:—

Drift front wings, 143.5 × 0.0285 × 2.42	= 9.90 lb.
„ rear wings, 29.5 × (0.043 - 0.242 × 0.0523) × 2.42	= 2.17 „
Tangential force at 3°	= 0.00 „
Head resistance, 11.70 × 2.42	= 28.31 „
Total resistance	= 40.38 lb.

Speed 22 miles per hour. Power = $\frac{40.38 \times 22}{375} = 2.36$ h.p. for the "thrust" or 4.72 h.p. for the motor. The weight being 189 lb, and the resistance 40.38 lb, the gliding angle of descent was: $\frac{40.38}{189} = \text{tangent of } 12^\circ$, which was verified by many experiments.

The following expressions, some of which have been given in the text, will be found useful in computing such projects, with the aid of the table above given:—

1. Wind force, $F = KV^2$
2. Pressure, $P = KV^2 S$.
3. Velocity, $V = \sqrt{\frac{W}{KS \eta \cos \alpha}}$
4. Surface S varies as $\frac{1}{V^2}$.
5. Normal, $N = KSV^2 \eta$.
6. Lift, $L = KSV^2 \eta \cos \alpha$.
7. Weight, $W = L = N \cos \alpha$.
8. Drift, $D = KSV^2 \eta \sin \alpha$.
9. Head area E, get an equivalent.
10. Head resistance, $H = EF$.
11. Tangential force, $T = Pa$.
12. Resistance, $R = D + H \pm T$.
13. Ft. lb, $M = RV$.
14. Thrust, h.p., = $\frac{RV}{\text{factor}}$

(o. c.)

Æther.—In the mechanical processes which we can experimentally modify at will, and which therefore we learn to apprehend with greatest fulness, whenever an effect on a body B is in causal connexion with a process instituted in another body A, it is usually possible to discover a mechanical connexion between the two bodies which allows the influence of A to be traced all the way across the intervening region. The question thus arises whether, in electric attractions across apparently empty space and in gravitational attraction across the celestial regions, we are invited or required to make search for some similar method of continuous transmission of the physical effect, or whether we should rest content with an exact knowledge of the laws according to which one body affects mechanically another body at a distance. The view that our knowledge in such cases may be completely represented by means of laws of action at a distance, expressible in terms of the positions (and possibly motions) of the interacting bodies without taking any heed of the intervening space, belongs to modern times. It could hardly have been thought of before Sir Isaac

Newton's discovery of the actual facts regarding universal gravitation. Although, however, gravitation has formed the most perfect instance of an influence completely expressible, up to the most extreme refinement of accuracy, in terms of laws of direct action across space, yet, as is well known, the author of this ideally simple and perfect theory held the view that it is not possible to conceive of direct mechanical action independent of means of transmission. In this belief he differed from his pupil Cotes, and from most of the great mathematical astronomers of the 18th century, who worked out in detail the task sketched by the genius of Newton. They were content with a knowledge of the truth of the principle of gravitation; instead of essaying to explain it further by the properties of a transmitting medium, they in fact modelled the whole of their natural philosophy on that principle, and tried to express all kinds of material interaction in terms of laws of direct mechanical attraction across space. If material systems are constituted of discrete atoms, separated from each other by many times the diameter of any of them, this simple plan of exhibiting their interactions in terms of direct forces between them would indeed be exact enough to apply to a wide range of questions, provided we could be certain that the laws of the forces depended only on the positions and not also on the motions of the atoms. The most important example of its successful application has been the theory of capillary action elaborated by Laplace; though even here it appeared, in the hands of Young, and in complete fulness afterwards in those of Gauss, that the definite results attainable by the hypothesis of mutual atomic attractions really reposed on much wider and less special principles—those, namely, connected with the modern doctrine of energy.

Idea of an Æther.—The wider view, according to which the hypothesis of direct transmission of physical influences expresses only part of the facts, is that all space is filled with physical activity, and that while an influence is passing across from a body A to another body B, there is some dynamical process in action in the intervening region, though it appears to the senses to be mere empty space. The question is whether we can represent the facts more simply by supposing the intervening space to be occupied by a medium which transmits physical actions after the manner that a continuous material medium, solid or liquid, transmits mechanical disturbance. Various analogies of this sort are open to us: for example, the way in which a fluid medium transmits pressure from one immersed solid to another—or from one vortex ring belonging to the fluid to another, which is a much wider and more suggestive case; or the way in which an elastic fluid like the atmosphere transmits sound; or the way in which an elastic solid transmits waves of transverse as well as longitudinal displacement. It is on our familiarity with modes of transmission such as these, and with the exact analyses of them which the science of mathematical physics has been able to make, that our predilection for filling space with an æthereal transmitting medium, constituting a universal connexion between material bodies, largely depends; perhaps ultimately it depends most of all, like all our physical conceptions, on the intimate knowledge that we can ourselves exert mechanical effect on outside bodies only through the agencies of our limbs and sinews. The problem thus arises, Can we form a consistent notion of such a connecting medium? It must be a medium which can be effective for transmitting all the types of physical action known to us: it would be worse than no solution to have one medium to transmit gravitation, another to transmit electric effects, another to transmit light, and so on. Thus the attempt to find out a constitution for the æther will involve a synthesis

or intimate correlation of the various types of physical agencies, which appear so different to us mainly because we perceive them through different senses. The evidence for this view, that all these agencies are at bottom connected together and parts of the same scheme, was enormously strengthened during the latter half of the 19th century by the development of a relation of simple quantitative equivalence between them; it has been found that we can define quantities relating to them, under the names of mechanical energy, electric energy, thermal energy, and so on, so that when one of them disappears it is replaced by the others to exactly equal amount. This single principle of energy has transformed physical science by making possible the construction of a network of ramifying connexions between its various departments: it thus stimulates the belief that these constitute a single whole, and encourages the search for the complete scheme of interconnexion of which the principle of energy and the links which it suggests form only a single feature.

Atomic Structure of Matter.—The greatest obstacle to such a search is the illimitable complexity of matter, as contrasted with the theoretical simplicity and uniformity of the physical agencies which connect together its different parts. It has been maintained since the times of the early Greek philosophers, and possibly even more remote ages, that matter is constituted of independent indestructible units, which cannot ever become divided by means of any mutual actions they can exert. Since the period, a century ago, when Dalton and his contemporaries constructed from this idea a scientific basis for chemistry, the progress of that subject has been wonderful beyond any conception that could previously have been entertained; and the atomic theory in some form appears now to be an indispensable part of the framework of physical science. Now this doctrine of material atoms is an almost necessary corollary to the doctrine of a universal æther. For if we held that matter is continuous, one of two alternatives would be open. We might consider that matter and æther can co-exist in the same space; this would involve the co-existence and interaction of a double set of properties, introducing great complication which would place any coherent scheme of physical action probably beyond the powers of human analysis. Or we might consider that æther exists only where matter is not, thus making it a very rare and subtle and elastic kind of matter; then we should have to assign these very properties to the matter itself where it replaces æther, in addition to its more familiar properties, and the complication would remain. The other course is to consider matter as formed of ultimate atoms, each the nucleus or core of an intrinsic modification impressed on the surrounding region of the æther; this might conceivably be of the nature of vortical motion of a liquid round a ring-core, thus giving a vortex atom, or of an intrinsic strain of some sort radiating from a core, which would give an electric atom. We recognize an atom only through its physical activities as manifested in its interactions with other atoms at a distance from it; this field of physical activity would be identical with the surrounding field of æthereal motion or strain that is associated with the atom, and is carried on along with it as it moves. Here then we have the basis of a view in which there are not two media to be considered, but one medium, homogeneous in essence and differentiated as regards its parts only by the presence of nuclei of intrinsic strain or motion—in which the physical activities of matter are identified with those arising from the atmospheres of modified æther which thus belong to its atoms. As regards laws of general physical interactions, the atom is fully represented by the constitu-

tion of this atmosphere, and its nucleus may be left out of our discussions; but in the problems of biology great tracts of invariable correlations have to be dealt with, which seem hopelessly more complex than any known or humanly possible physical scheme. To make room for these we have to remember that the atomic nucleus has remained entirely undefined and beyond our problem; so that what may occur, say when two molecules come into close relations, is outside physical science—not, however, altogether outside, for we know that when the vital *nexus* in any portion of matter is dissolved, the atoms will remain, in their number, and their atmospheres, and all inorganic relations, as they were before vitality supervened.

Nature of Properties of Material Bodies.—It thus appears that the doctrine of atomic material constitution and the doctrine of a universal æther stand to each other in a relation of mutual support; if the scheme of physical laws is to be as precise as observation and measurement appear to make it, both doctrines are required in our efforts towards synthesis. Our direct knowledge of matter can, however, never be more than a rough knowledge of the general average behaviour of its molecules; for the smallest material speck that is sensible to our coarse perceptions contains myriads of atoms. The properties of the most minute portion of matter which we can examine are thus of the nature of averages. We may gradually invent means of tracing more and more closely the average drifts of translation or orientation, or of changes of arrangement, of the atoms; but there will always remain an unaveraged residue devoid of any recognized regularity, which we can only estimate by its total amount. Thus, if we are treating of energy, we can separate out mechanical and electric and other constituents in it; and there will be a residue of which we know nothing except its quantity, and which we may call thermal. This merely thermal energy—which is gradually but very slowly being restricted in amount as new subsidiary organized types become recognized in it—though transmutable in equivalent quantities with the other kinds, yet is so only to a limited extent; the tracing out of the laws of this limitation belongs to the science of thermodynamics. It is the business of that science to find out what is the greatest amount of thermal energy that can possibly be recoverable into organized kinds under given circumstances. The discovery of definite laws in this region might at first sight seem hopeless; but the argument rests on an implied postulate of stability and continuity of constitution of material substances, so that after a cycle of transformations we expect to recover them again as they were originally—on the postulate, in fact, that we do not expect them to melt out of organized existence in our hands. The laws of thermodynamics, including the fundamental principle that a physical property, called temperature, can be defined, which tends towards uniformity, are thus relations between the properties of types of material bodies that can exist permanently in presence of each other; why they so maintain themselves remains unknown, but the fact gives a *point d'appui*. Returning now to the æther, on our present point of view no such complications there arise; it must be regarded as a continuous uniform medium free from any complexities of atomic aggregation, whose function is confined to the transmission of the various types of physical effect between the portions of matter. The problem of its constitution is thus one which can be attacked and continually approximated to, and which may possibly be definitely resolved. It has to be competent to transmit the transverse waves of light and electricity, and the other known radiant and electric actions; the way in which this is done is now in the main known, though there are still questions as to the

mode of expression and formulation of our knowledge, and also as regards points of detail. This great advance, which is the result of the gradual focussing of a century's work in the minute exploration of the exact laws of optical and electric phenomena, clearly carries with it deeper insight into the physical nature of matter itself and its modes of inanimate interaction.

If we rest on the synthesis here described, the energy of the matter, even the thermal part, appears largely as potential energy of strain in the æther, which interacts with the kinetic energy associated with disturbances involving finite velocity of matter. It may, however, be maintained that an ultimate analysis would go deeper, and resolve all phenomena of elastic resilience into consequences of the kinetic stability of steady motional states, so that only motions, but not strains, would remain. On such a view the æther might conceivably be a perfect fluid, its fundamental property of elastic reaction arising (as suggested by Kelvin and FitzGerald) from a structure of tangled or interlaced vortex filaments pervading its substance, which might conceivably arrange themselves into a stable configuration and so resist deformation. This raises the further question as to whether the transmission of gravitation can be definitely recognized among the properties of an ultimate medium; if so, we know that it must be associated with some feature, perhaps very deep-seated, or on the other hand perhaps depending simply on incompressibility, which is not sensibly implicated in the electric and optical activities. With reference to all such further refinements of theory, it is to be borne in mind that the perfect fluid of hydrodynamic analysis is not a merely passive inert *plenum*; it is also a *continuum*, with the property that no finite internal slip or discontinuity of motion can ever arise in it through any kind of disturbance; and this property must be postulated, as it cannot be explained.

Motion of Material Atoms through the Æther.—An important question arises whether, when a material body is moved through the æther, the nucleus of each atom carries some of the surrounding æther along with it; or whether it practically only carries on its strain-form or physical atmosphere, which is transferred from one portion of æther to another after the manner of a shadow, or rather like a loose knot which can slip along a rope without the rope being required to go with it. We can obtain a pertinent illustration from the motion of a vortex ring in a fluid; if the circular core of the ring is thin compared with its diameter, and the vorticity is not very great, it is the vortical state of motion that travels across the fluid without transporting the latter bodily with it except to a slight extent very close to the core. We might thus imagine a structure formed of an aggregation of very thin vortex rings, which would move across the fluid without sensibly disturbing it; on the other hand, if formed of stronger vortices, it may transport the portion of the fluid that is within its own structure along with it as if it were a solid mass, and therefore also push aside the surrounding fluid as it passes. The motion of the well-known steady spherical vortex is an example of the latter case.

Convection of Optical Waves.—The nature of the motion, if any, that is produced in the surrounding regions of the æther by the translation of matter through it, can be investigated by optical experiment. The obvious body to take in the first instance is the Earth itself, which on account of its annual orbital motion is travelling through space at the rate of about 18 miles per second. If the surrounding æther is thereby disturbed, the waves of light arriving from the stars will partake of its movement; the ascertained phenomena of the astronomical aberration of light show that the rays travel to the observer, across this disturbed æther near the Earth, in

straight lines. Again, we may split a narrow beam of light by partial reflection from a transparent plate, and recombine the constituent beams after they have traversed different circuits of nearly equivalent lengths, so as to obtain interference fringes. The position of these fringes will depend on the total retardation of the one beam with respect to the other; and thus it might be expected to vary with the direction of the Earth's motion relative to the apparatus. But it is found not to vary at all, even up to the second order of the ratio of the Earth's velocity to that of light. It has in fact been found, with the very great precision of which optical experiment is capable, that all terrestrial optical phenomena—reflection, refraction, polarization linear and circular, diffraction—are entirely unaffected by the direction of the Earth's motion; and this is our main experimental clue.

We pass on now to the theory. We shall make the natural supposition that motion of the æther, say with velocity (u, v, w) at the point (x, y, z) , is simply superposed on the velocity V of the optical undulations through that medium, the latter not being intrinsically altered. Now the direction and phase of the light are those of the ray which reaches the eye; and by Fermat's principle, established by Huygens for undulatory motion, the path of a ray is that track along which the disturbance travels in least time, in the restricted sense that any alteration of any *short* reach of the path will increase the time. Thus the path of the ray when the æther is at rest is the curve which makes $\int ds/V$ least; but when it is in motion it is the curve which makes $\int ds/(V + lu + mv + nw)$ least, where (l, m, n) is the direction vector of ds . The latter integral becomes, on expanding in a series,

$$\int ds/V - \int (udx + vdy + wdz)/V^2 + \int (udx + vdy + wdz)^2/V^3 ds + \dots,$$

since $lds = dx$. If the path is to be unaltered by the motion of the æther, as the law of astronomical aberration suggests, this must differ from $\int ds/V$ by terms not depending on the path—that is, by terms involving only the beginning and end of it. In the case of the free æther V is constant; thus, if we neglect squares like $(u/V)^2$, the condition is that $udx + vdy + wdz$ be the exact differential of some function ϕ . If this relation is true along all paths, the velocity of the æther must be of irrotational type, like that of frictionless fluid. Moreover, this is precisely the condition for the absence of interference between the component of a split beam; because, the time of passage being to the first order

$$\int ds/V - \int (udx + vdy + wdz)/V^2,$$

the second term will then be independent of the path (ϕ being a single valued function) and therefore the same for the paths of both the interfering beams. If therefore the æther can be put into motion, we conclude that such motion, in free space, must be of strictly irrotational type.

But our experimental data are not confined to free space. If c is the velocity of radiation in free space and μ the refractive index of a transparent body, $V = c/\mu$; thus it is the expression $c^{-2} \int \mu^2 (u'dx + v'dy + w'dz)$ that is to be integrable exactly, where now (u', v', w') is what is added to V owing to the velocity (u, v, w) of the medium. As however our terrestrial optical apparatus is now all in motion along with the matter, we must deal with the rays relative to the moving system, and to them also Fermat's principle clearly applies; thus $V + (lu' + mv' + nw')$ is here the velocity of radiation in the direction of the ray, but relative to the moving material system. Now the expression above given cannot be integrable exactly, under all circumstances and whatever be the axes of co-ordinates, unless $(\mu^2 u', \mu^2 v', \mu^2 w')$ is the gradient of a continuous function. In the simplest case, that of uni-

form translation, these components of the gradient will each be constant throughout the region; at a distant place in free æther where there is no motion, they must thus be equal to $-u, -v, -w$, as they refer to axes moving with the matter. Hence the paths and times of passage of all rays relative to the material system will not be altered by a uniform motion of the system, provided the velocity of radiation relative to the system, in material of index μ , is diminished by μ^{-2} times the velocity of the system in the direction of the radiation, that is, provided the absolute velocity of radiation is increased by $1 - \mu^{-2}$ times the said velocity; this involves that the free æther for which μ is unity shall remain at rest. This statement constitutes the famous hypothesis of Fresnel, which thus ensures that all phenomena of ray-path and refraction, and all those depending on phase, shall be unaffected by uniform convection of the material medium, in accordance with the results of experiment.

Is the Æther Stationary or Mobile?—This theory secures that the times of passage of the rays shall be independent of the motion of the system, only up to the first order of the ratio of its velocity to that of radiation. But a classical experiment of Michelson, in which the ray-path was wholly in air, showed that the independence extends to higher orders. This result is inconsistent with the æther remaining at rest, unless we assume that the dimensions of the moving system depend, though to an extent so small as to be not otherwise detectable, on its orientation with regard to the æther that is streaming through it. It is however in complete accordance with a view that would make the æther near the Earth fully partake in its orbital motion—a view which the null effect of convection on all terrestrial optical and electrical phenomena also strongly suggests. But the æther at a great distance must in any case be at rest; while the facts of astronomical aberration require that the motion of that medium must be irrotational. These conditions cannot be consistent with sensible convection of the æther near the Earth without involving discontinuity in its motion at some intermediate distance: so that we are thrown back on the previous theory.

Another powerful reason for taking the æther to be stationary is afforded by the character of the equations of electrodynamics; they are all of linear type, and superposition of effects is possible. Now the kinetics of a medium in which the parts can have finite relative motions will lead to equations which are not linear—as, for example, those of hydrodynamics—and the phenomena will be far more complexly involved. It is true that the theory of vortex rings in hydrodynamics is of a simpler type; but electric currents cannot be likened to permanent vortex rings, because their circuits can be broken and the element of steadiness on which the simplicity depends thereby destroyed.

Dynamical Theories of the Æther.—The analytical equations which represent the propagation of light in free æther, and also in æther modified by the presence of matter, were originally developed on the analogy of the equations of propagation of elastic effects in solid media (See WAVE THEORY, *Ency. Brit.* vol. xxiv.). Various types of elastic solid medium have thus been invented to represent the æther, without complete success in any case. In MacCullagh's hands the correct equations were derived from a single energy formula by the principle of least action; and while the validity of this dynamical method was maintained, it was frankly admitted that no mechanical analogy was forthcoming. When Clerk Maxwell pointed out the way to the common origin of optical and electrical phenomena, these equations naturally came to repose on an electric basis, the connexion having been first definitely exhibited by FitzGerald in 1878; and according as the

independent variable was one or other of the vectors which represent electric force, magnetic force, or electric polarity, they took the form appropriate to one or other of the elastic theories above mentioned.

In this place it must suffice to indicate the gist of the more recent developments of the electro-optical theory, which involve the dynamical verification of Fresnel's hypothesis regarding optical convection and the other relations above described. The æther is taken to be at rest; and the strain-forms belonging to the atoms are the electric fields of the intrinsic charges, or electrons, involved in their constitution. When the atoms are in motion these strain-forms produce straining and unstraining in the æther as they pass across it, which in its motional or kinetic aspect constitutes the resulting magnetic field; as the strains are slight the coefficient of inertia here involved must be great. True electric current arises solely from convection of the atomic charges or electrons; this current is therefore not restricted as to form in any way. But when the rate of change of æthereal strain—that is, of (f,g,h) specified as Maxwell's electric displacement in free æther—is added to it, an analytically convenient vector (u,v,w) is obtained which possesses the characteristic property of being circuital like the flow of an incompressible fluid, and has therefore been made fundamental in the theory by Maxwell under the name of the total electric current.

As already mentioned, all efforts to assimilate optical propagation to transmission of waves in an ordinary solid medium have failed; and though the idea of regions of intrinsic strain, as for example in unannealed glass, is familiar in physics, yet on account of the absence of mobility of the strain no attempt had been made to employ them to illustrate the electric fields of atomic charges. The idea of MacCullagh's æther, and its property of purely rotational elasticity which had been expounded objectively by Rankine, was therefore much vivified by Lord Kelvin's specification in 1889 of a material gyrostatically constituted medium which would possess this character. More recently a way has been pointed out in which a mobile permanent field of electric force could exist in such a medium so as to travel freely in company with its nucleus or intrinsic charge—the nature of the mobility of the latter, as well as its intimate constitution, remaining unknown.

A dielectric substance is electrically polarized by a field of electric force, the atomic poles being made up of the displaced positive and negative intrinsic charges in the atom: the polarization per unit volume (f',g',h') may be defined on the analogy of magnetism, and $d/dt(f',g',h')$ thus constitutes true electric current of polarization, *i.e.*, of electric separation in the molecules, specified per unit volume. The convection of a medium thus polarized involves electric disturbance, and therefore must contribute to the true electric current; the determination of this constituent of the current is the most delicate point in the investigation. The usual definition of the component current in any direction, as the net amount of electrons which crosses, towards the positive side, an element of surface *fixed in space* at right angles to that direction, per unit area per unit time, here gives no definite result. The establishment and convection of a single polar atom constitutes in fact a *quasi*-magnetization, the negative poles completing the current circuits of the positive ones. But in the transition from molecular theory to the electrodynamics of extended media, all magnetism has to be replaced by a distribution of current; the latter being now specified by volume as well as by flow, $(u,v,w)\delta r$ is the current in the element of volume δr . In the present case the total dielectric contribution to this current works out to be the change per unit time in the

electric separation in the molecules of the element of volume, as it moves *uniformly* with the matter, all other effects being compensated molecularly without affecting the propagation.¹ On subtracting from this total the current of establishment of polarization $d/dt(f',g',h')$, already formulated above, there remains $v d/dx(f',g',h')$ as the current of convection of polarization when the convection is taken for simplicity to be in the direction of the axis of x with velocity v . The polarization itself is determined from the electric force (P,Q,R) by the usual statical formula

$$(f',g',h') = \frac{K-1}{4\pi c^2} (P,Q,R),$$

because any change of the dielectric constant K arising from the convection of the material through the æther must be independent of the sign of v and therefore be of the second order. Now the *electric force* (P,Q,R) is the force acting on the electrons of the medium moving with velocity v ; consequently by Faraday's electrodynamic law

$$(P,Q,R) = (P',Q' - vc, R' + v\delta)$$

where (P',Q',R') is the force that would act on electrons at rest, and (a,b,c) is the magnetic induction. The latter force is, by Maxwell's hypothesis or by the dynamical theory of an æther pervaded by electrons, the same as that which strains the æther, and may be called the *æthereal force*; it thereby produces an æthereal electric displacement, say (f,g,h) , according to the relation

$$(f,g,h) = (4\pi c^2)^{-1} (P',Q',R'),$$

in which c is a constant belonging to the æther, which turns out to be the velocity of light. The current of æthereal displacement $d/dt(f,g,h)$ is what adds on to the true electric current to produce the total circuital current of Maxwell.

We have now to substitute these data in the universally valid circuital relations—namely, (i) line integral of magnetic force round a circuit is equal to 4π times the current through its aperture, which may be regarded as a definition of the constitution of the æther and its relation to the electrons involved in it; and (ii) line integral of the electric force belonging to any material circuit (*i.e.*, acting on the electrons situated on it which move with the velocity of the matter) is equal to *minus* the time-rate of change of the magnetic induction through that circuit as it moves with the matter, this being a dynamical consequence of the æthereal constitution assigned in (i).

We may now, as is somewhat the more natural course in the terrestrial application, take axes (x,y,z) which move with the matter; but the current must be invariably defined by the flux across surfaces fixed in space, so that we may say that relation (i) refers to a circuit fixed in space, while (ii) refers to one moving with the matter. These circuital relations, when expressed analytically, are then for a dielectric medium of types

$$\frac{d\gamma}{dy} - \frac{d\beta}{dz} = 4\pi u, \dots, \dots,$$

where $(u,v,w) = \left(\frac{d}{dt} + v \frac{d}{dx} \right) (f',g',h') + \frac{d}{dt} (f,g,h),$

and $\frac{dR}{dy} - \frac{dQ}{dz} = -\frac{da}{dt}, \dots, \dots,$

where, when magnetic quality is inoperative, the magnetic induction (a,b,c) is identical with the magnetic force (α,β,γ) .

These equations determine all the phenomena. They take this simple form, however, only when the movement of the matter is one of translation. If v varies with respect to locality, or if there is a velocity of convection (p,q,r) variable with respect to direction and position, the

¹ See Lorentz, *loc. cit. infra*; Larmor, *Æther and Matter*, p. 262 and *passim*.

analytical expression of the relation (ii) assumes a more complex form; we thus derive the most general equations of electrodynamic propagation for matter treated as continuous, anyhow distributed and moving in any manner.

For the simplest case of polarized waves travelling parallel to the axis of x , with the magnetic oscillation γ along z and the electric oscillation Q along y , all the quantities are functions of x and t alone; the total current is along y and given with respect to our moving axes by

$$v = \left(\frac{d}{dt} - v \frac{d}{dx} \right) \frac{Q + v\gamma}{4\pi c^2} + \frac{d}{dt} \left(\frac{K-1}{4\pi c^2} \right) Q;$$

also the circuital relations here reduce to

$$-\frac{d\gamma}{dx} = 4\pi v, \quad \frac{dQ}{dx} = -\frac{d\gamma}{dt};$$

thus

$$\frac{d^2 Q}{dx^2} = 4\pi \frac{dv}{dt}$$

giving, on substitution for v ,

$$(c^2 - v^2) \frac{d^2 Q}{dx^2} = K \frac{d^2 Q}{dt^2} - 2v \frac{d^2 Q}{dx dt}.$$

For a simple wave-train, Q varies as $\sin m(x - Vt)$, leading on substitution to the velocity of propagation V relative to the moving material, by means of the equation $KV^2 + 2vV = c^2 - v^2$; this gives, to the first order of v/c , $V = c/K^{\frac{1}{2}} - v/K$, which is in accordance with Fresnel's law. Trains of waves nearly but not quite homogeneous as regards wave-length will as usual be propagated as wave-groups travelling with the slightly different velocity $d(V\lambda^{-1})/d\lambda^{-1}$, the value of K occurring in V being a function of λ determined by the law of optical dispersion of the medium.

For purposes of theoretical discussions relating to moving radiators and reflectors, it is important to remember that the dynamics of this theory of electrons involves the neglect of terms of the order $(v/c)^2$, not merely in the value of K but throughout.

The modification of the spectrum of a radiating gas by a magnetic field, such as would result from the hypothesis that the radiators are the system of revolving or oscillating electrons in the molecule, was detected by Zeeman in 1896; more minute investigation has largely confirmed the predictions as to its character that were made by H. A. Lorentz and others on the basis of the theoretical ideas here sketched.

Afforestation. See FORESTS.

Affreightment.—*Contract of Affreightment* is the expression usually employed to describe the contract between a shipowner and some other person called the freighter, by which the shipowner agrees to carry goods of the freighter in his ship, or to give to the freighter the use of the whole or part of the cargo-carrying space of the ship for the carriage of his goods on a specified voyage or voyages, or for a specified time; the freighter on his part agreeing to pay a specified price, called "freight," for the carriage of the goods or the use of the ship. A ship may be let like a house to some person who takes possession and control of it for a specified term. The person who hires a ship in this way occupies during the currency of his term the position of shipowner. The contract by

which a ship is so let may be called a *charter-party*; but it is not, properly speaking, a contract of affreightment, and is mentioned here only because it is necessary to remember the distinction between a *charter-party* of this kind, which is sometimes called a demise of the ship, and a *charter-party* which is a form of contract of affreightment, as will hereinafter appear.

The law with regard to the contract of affreightment is, of course, a branch of the general law of contract. The rights and obligations of the shipowner and the freighter depend, as in the case of all parties to contracts, upon the terms of the agreement entered into between them. The law, however, interferes to some extent in regulating the effect to be given to contracts. Certain contracts are forbidden by the law, and being illegal are, therefore, incapable of enforcement. The most important example of illegality in the case of contracts of affreightment is when the contract involves trading with an enemy. The law interferes again with regard to the interpretation of the contract. The meaning to be given to the words of the contract, or, in other words, its construction, when a dispute arises about it, must be determined by the judge or court. The result is, that certain more or less common clauses in contracts of affreightment have come before the courts for construction, and the decisions in these cases are treated practically, though not perhaps quite logically, as rules of law determining the sense to be put upon certain forms of expression in common use in shipping contracts. A third way in which the law interferes is by laying down certain rules by which the rights of the parties are to be regulated in the absence of any express stipulation with regard to the matter dealt with by such rules. This is done either by statutory enactment, as by that part (Part VIII.) of the Merchant Shipping Act, 1894, which deals with the liability of shipowners; or by established rules of the unwritten law, the "common law" as it is called, as for instance, the rule that the common carrier is absolutely responsible for the safe delivery of the goods carried, unless it is prevented by the act of God or the King's enemies. These rules of law, whether common law or statute law, regulating the obligations of carriers of goods by sea, are of most importance in cases which are uncommon though not unknown at the present day, in which there is an affreightment without any written agreement of any kind. It will, therefore, be convenient to consider first cases of this kind where there is no express agreement, oral or written, except as to the freight and destination of the goods, and where consequently the rights and obligations of the parties as to all other terms of carriage depend wholly upon the rules of law, remembering always that these same rules apply when there is a written contract, except in so far as they are qualified or negated by the terms of such contract.

Rules of law.

The rules of the common or ancient customary law of England with regard to the carriage of goods were no doubt first considered by the courts and established with regard to the carriage of goods by common carriers on land. These rules were applied to common carriers by water, and it may now be taken to be the general rule that shipowners who carry goods by sea are by the English law subject to the liabilities of common carriers. (See as to the grounds and precise extent of this doctrine the judgments in *Liver Alkali Company v. Johnson*, L.R., 7 Ex. 267, and *Nugent v. Smith*, 1 C.P.D. 423.) In practice goods are not often shipped without a written contract or acknowledgment of the terms upon which they are to be carried. For each separate consignment or parcel of goods shipped a *bill of lading* is almost invariably given, and when a whole cargo is agreed to be carried

the terms are set out in a document called a *charter-party*, signed by or on behalf of the shipowner on the one part, and the shipper, who is called the *charterer*, on the other part. But at present we are considering the relations of shipowner and shipper independently of any express contract, as in a case when goods are shipped and received to be carried to the place to which the ship is bound for a certain freight, but without any further agreement as to the terms of carriage. In such a case the rights of the parties depend on the rules of law, or, which is much the same thing, upon the

In default of express contract.

warranties or promises which though not expressed must, as the courts have held, be implied as arising from the relation between the parties as shipper and carrier. The obligations on the one side and the other may be defined shortly to be as follows:—The shipper must not ship goods of a nature or in a condition which he knows, or ought, if he used reasonable care, to know to be dangerous to the ship, or to other goods, unless the shipowner has notice of or has sufficient opportunity to observe their dangerous character. The shipper must be prepared, without notice from the shipowner, to take delivery of his goods with reasonable despatch on the arrival of the ship at the place of destination, being ready there to discharge in some usual discharging place. The shipper must pay the agreed freight, and will not be entitled to claim delivery until the freight has been paid. In other words, the shipowner has a *lien* on the goods carried for the freight payable in respect of the carriage. On the other hand the obligation upon the shipowner is first and foremost to deliver safely at their destination the goods shipped, and this obligation is, by the common law, subject to this exception only that the shipowner is not liable for loss or damage caused by the act of God or the King's enemies; but by statute (Merchant Shipping Act, 1894, Part VIII.) it is further qualified to this extent that the shipowner is not liable for loss, happening without his actual fault or privity, by fire on board the ship, or by the robbery, or embezzlement of, or making away with gold, or silver, or jewellery, the true nature and value of which have not been declared in writing at the time of shipment; and, further, the shipowner is not liable for damage to or loss of goods or merchandise beyond an aggregate amount, not exceeding eight pounds per ton for each ton of the ship's tonnage. The shipowner is bound by an implied undertaking, or, in other words, is made responsible by the law as if he had entered into an express undertaking: (1) that the ship is seaworthy; (2) that she shall proceed upon the voyage with reasonable despatch, and shall not deviate without necessity from the usual course of the voyage.

It is not our purpose in this article to discuss minute or doubtful questions; but in their general outline the obligations of shipper and shipowner, where no terms of carriage have been agreed, except as to the freight and destination of the goods, are such as have been described above. The importance of appreciating clearly this view of the relations of shipper and shipowner arises from the fact that these fundamental rules apply to all contracts of affreightment, whether by bill of lading, charter-party, or otherwise, except in so far as they are modified or negatived by the express terms of the contract.

Bills of Lading.

The document signed by the master or agent for the shipowner, by which are acknowledged the shipment of a parcel of goods and the terms upon which it is to be carried, is called a Bill of Lading. Very many different forms of bills of lading are used. For the purpose of illustration the following form (from Mr Scrutton's book on *Charter-*

parties and Bills of Lading) has been selected as a sample:—

Shipped, in apparent good order and condition by _____ in and upon the good Vessel called the _____ now lying in the port of _____ and bound for _____, with liberty to call at any ports in any order, to sail without Pilots, and to tow and assist Vessels in distress, and to deviate for the purpose of saving life or property; _____ and to be delivered in the like good order and condition at the aforesaid port of _____ unto _____ or to his or their assigns, freight and all other conditions as per Charter Party. The act of God, perils of the sea, fire, barratry of the Master and Crew, enemies, pirates, and thieves, arrests, and restraints of princes, rulers, and people, collisions, stranding, and other accidents of navigation excepted, even when occasioned by negligence, default, or error in judgment of the Pilot, Master, Mariners, or other servants of the Ship-owners.

Ship not answerable for losses through explosion, bursting of boilers, breakage of shafts, or any latent defect in the machinery or hull, not resulting from want of due diligence by the Owners of the Ship, or any of them, or by the Ship's Husband or Manager.

General Average payable according to York-Antwerp Rules.

In Witness whereof, the Master or Agent of the said Ship hath affirmed to three Bills of Lading, all of this tenor and date, drawn as first, second and third, one of which Bills being accomplished, the others to stand void.

Dated in this _____ day of _____ 188 _____.

The Bill of Lading is an acknowledgment of the shipment of goods in a named vessel for carriage to a specified destination on terms set forth in the document. It is usually signed by the master of the vessel, but very commonly by the agents of the shipowner or sometimes of the charterers of the vessel. A vessel may be employed by its owners to earn freight in various ways: (1) It may be placed, as it is said, on the berth as a general ship, to receive cargo from any shippers who may desire to send goods to the port, or one of the ports, to which the vessel is bound. The mate or chief officer usually superintends the loading, and, as goods are shipped, a *mate's receipt* is given as an acknowledgment of the shipment. The *mate's receipt* is afterwards exchanged for the *bill of lading*. In the case of a shipment by a general ship the bill of lading is the evidence and memorandum of the contract between the shipowner and the shipper; (2) a shipper may, however, require the whole cargo space of the vessel to carry, for example, a full cargo of grain. In such a case the vessel will be chartered by the shipowner to the shipper, and the contract will be the charter-party. Even in such a case a bill or bills of lading will usually be given to enable the shipper to deal more conveniently with the goods by way of sale or otherwise. By the ancient custom of merchants recognized and incorporated in the law, the bill of lading is a document of title, representing the goods themselves, by the transfer of which symbolical delivery of the goods may be made. But when a cargo is shipped under a charter-party, although bills of lading may be given to the charterer, it is the charter-party, and not the bills of lading, which constitutes the record of the contract between the parties—of *charter-parties* we shall treat below. (3) There is a third class of case which is a combination of the two with which we have dealt above. A vessel is very commonly chartered by her owner to a charterer who has no intention to ship and does not ship any cargo on his own account, but places the vessel on the berth to receive cargo from shippers who ship under bills of lading. The charterer receives the bill of lading freight and pays the charter-party freight, his object being of course to obtain a total bill of lading freight in excess of the chartered freight, and so make a profit. The master, although he usually remains the servant of the shipowner during the term of the charter-party, acts nevertheless under the directions and on behalf of the charterer in signing bills of lading. The legal effect of this situation is that shippers who ship goods under bills of lading without knowledge of the

terms of the charter-party are entitled to look to the shipowner as the person responsible to them for the safe carriage of their goods. This right depends essentially on the fact that the master who signs the bills of lading, although in doing so he is acting for the charterer, remains nevertheless the servant of the shipowner, who is not allowed to deny as against third persons, who do not know the relations between the charterer and the shipowner, that his servant, the master of the ship, has the ordinary authority of a master to bind his owner by signing bills of lading.

The forms of bills of lading vary very much, and their clauses have been the subject of judicial consideration and decision in a vast number of reported cases. The essential particulars, or at all events those common to all bills of lading, may be stated as follows:

1. The name of the shipper.
2. The name of the ship.
3. The place of loading and destination of the ship.
4. A description of the goods shipped.
5. The place of delivery.
6. The persons to whom delivery is to be made.
7. The freight to be paid.
8. The excepted perils.
9. The shipowner's lien.

The description of (1) the shipper, and (2) the ship, calls for no remark. The (3) description of the voyage is important, because there is, as we have already explained, an implied undertaking by the shipowner in every contract of carriage not unnecessarily to deviate from the ordinary route of the voyage upon which the goods are received to be carried. The consequences of a deviation are serious, inasmuch as the shipowner is liable, not only for any loss or damage which the shipper suffers in consequence of the deviation, but for any loss of goods which occurs after the deviation, even though such loss is caused by one of the excepted perils. The only exception to this rule is that a deviation may be made to save life, but not to save property. It is, however, very usual to qualify the strictness of this implied undertaking by introducing in the bill of lading certain "liberties" to deviate, as, for example, in the form given above, "liberty to call at any ports in any order, to tow and assist vessels in distress, and to deviate for the purpose of saving life and property." The nature and extent of the liberty will depend on the words of the contract. The inclination of English courts has been to construe clauses giving a liberty to deviate somewhat strictly against the shipowner.

The (4) importance of the description of the goods shipped and their condition is obvious, as the contract is to deliver them as described and in the like good condition, subject, of course, to the exceptions. It must, however, be noted, that, as against the master or person who has himself signed the bill of lading, the description therein of the goods shipped is absolutely conclusive. But as against the shipowner, unless he has himself signed the bill of lading, the description of the goods shipped is not conclusive. It is evidence as against him that the goods described were shipped, but he is allowed to rebut this evidence by proving, if he can, that the goods mentioned, or some of them, were not in fact shipped.

As to (5) the place of delivery, very serious questions frequently arise. Primarily, of course, the shipowner is bound to deliver at the place named. Should he be prevented by some obstacle or difficulty which is of a temporary nature, the vessel must wait, and delivery must be made as soon as possible. Where, however, the obstacle is permanent, or at all events such as must cause unreasonable delay, having regard to the nature of the adventure, the shipowner is excused from delivery at the place named

in the bill of lading, provided the difficulty arises from an excepted peril, or in consequence of delivery at the place named being forbidden by the law of England, as may happen, for example, in the case of a declaration of war between Great Britain and the state in which the port named in the bill of lading is situate. A party to a contract cannot be held liable for breaking his contract if its performance has become illegal. There may be other cases in which, from the circumstances of the voyage and adventure, it must be inferred that the parties intended the performance of the contract to be conditional on the existence at the time of performance of a certain state of things, the non-existence of which would render performance impossible. For instance, if the port named in the bill of lading became permanently closed and inaccessible to shipping in consequence of an earthquake, it would probably be held that the continued existence of the place named as a port was an implied condition of the contract, and that the shipowner was excused. Where, however, the performance of the contract remains lawful, and is not excused by the express terms of the contract, or by some implied condition, the shipowner is liable for any loss or damage suffered by the shipper by reason of his goods not being delivered at the named place, even though such delivery has become impossible. There is another reason why the precise description of the place of delivery often becomes important. It is only on the arrival of the ship at the place described as the place of delivery that the obligation of the consignee of the goods to take delivery commences. Delay involves considerable loss and expense to the shipowner. The shipper or consignee is not responsible for any delay which occurs before the ship has arrived at the place of delivery described in the bill of lading.

(6) The goods may be deliverable by the terms of the bill of lading to a named consignee, and to him only, but more usually they are made deliverable to the "order or assigns" of the named consignee or of the shipper. If the goods are made deliverable to order or assigns the bill of lading is a negotiable instrument, or, in other words, the right to the goods, and the rights and liabilities under the contract contained in the bill of lading, may be transferred by indorsement and delivery of the document. When an indorsement has once been made by the shipper or consignee writing his name and nothing more on the back of the bill of lading, the rights in and under it may be transferred from hand to hand by mere delivery. A bill of lading so indorsed is said to be indorsed "in blank." But the shipper or consignee may restrict the negotiability of the bill of lading by indorsing it not "in blank," but with a direction requiring delivery to be made to a particular person or indorsee, or to his order. This is called an indorsement "in full." When an indorsement has been made "in full" to a named indorsee or order, such indorsee must again indorse "in blank" or "in full" to effect a new transfer of the rights in the bill of lading.

(7) The amount or rate of *freight* payable is stated in the bill of lading, either expressly, or, not uncommonly when the freight under the bill of lading is the same as under the charter-party, by reference to the charter-party. A common form of such reference is "freight and other conditions, as per charter-party." It may here be mentioned that this form of words does not incorporate in the contract under the bill of lading all the terms and conditions of the charter-party, but only those which apply to the person who is to take delivery, and relate to matters *ejusdem generis*, or similar to the payment of freight, such as demurrage and the like. The conditions of the charter-party thus incorporated do not include, for instance, the exceptions in the charter-party so as to add them to the

exceptions in the bill of lading. Freight, unless it is otherwise provided by the contract, is payable only on delivery of the goods at their destination. If the voyage is interrupted and its completion becomes impossible, the shipowner cannot claim payment of freight even *pro rata itineris*. He loses his freight altogether. This is so even when the completion of the voyage is prevented by causes for which the shipowner is not responsible, such as the act of God or the King's enemies, or perils which are within the express exceptions in the bill of lading. When the voyage is interrupted by accident, and indeed in any case, the goods may, by agreement between the shipowner and the consignee, be delivered at some place short of their destination upon payment of a freight *pro rata*; that is to say, proportional to the length of voyage accomplished, and such an agreement may be implied in certain circumstances from the conduct of the consignee in taking delivery before they arrive at their destination. In all such cases it will be a question of fact whether the goods were in fact delivered upon the terms, express or implied, that freight *pro rata* should be paid. As a rule such an agreement would not be implied where the shipowner is unable or unwilling to forward the goods to their destination, and the owner of the goods, therefore, has no option but to take delivery of them there.

When the ship is disabled and cannot proceed, or she is prevented by some obstacle from proceeding to the place of delivery named in the bill of lading, and the shipowner is unwilling or unable to forward the goods by another ship, even though he may be excused for his failure to carry the goods to their destination, he is not entitled to be paid any part of the freight; and the consignee is entitled to have the goods delivered to him either at the place where the vessel has taken refuge in her disabled condition, or, if the obstacle arises without disablement of the vessel, at the place which is nearest and most reasonably convenient at the time and in the circumstances when the further prosecution of the voyage has to be abandoned. On the other hand, after the goods have been shipped, so long as the shipowner is ready and willing to carry the goods to their destination, or, if the ship is disabled, to forward them to their destination by some other ship without unreasonable delay, the owner of the goods cannot require the goods to be delivered to him at any place short of their destination without payment of the full freight. Sometimes the freight, either wholly or in part, is made payable *in advance*. If freight payable in advance has become due, even though the ship is lost before it is paid, it must, in the absence of some special provision to the contrary, still be paid, and freight already paid in advance does not become repayable because the goods do not reach their destination. If, however, goods upon which freight has been paid in advance are lost, and the shipowner is liable for their loss, the amount of freight paid in advance must be taken into account in assessing the damage recoverable from the shipowner.

(8) There is no part of the bill of lading which is of greater practical importance or which demands more careful consideration by shipowner and shipper alike than that which sets forth the excepted perils; those perils, in other words, or causes of loss for which the shipowner is to be exempt from liability. By the common law, as we have seen, the exemption of the carrier, apart from express contract, extended only to loss by the act of God or the King's enemies. The expression "act of God" requires a word of explanation. It will be sufficient to say that it is not synonymous with *force majeure*; but it includes every loss by *force majeure* in which human agency, by act or negligence, has had no part. The list of excepted perils varies much in different forms of bills of lading.

In the older forms it usually included perils of the seas, robbers and pirates, restraint of princes and rulers, fire and barratry (that is, wilful wrongdoing) of the master and crew. The list, however, has grown in modern times, and is still growing; the tendency being to exempt the shipowner from liability for all loss which does not arise from his own personal default, or from the negligence of his managers or agents in failing to provide a vessel seaworthy and fit for the voyage at its commencement. It is important to point out in this connexion that there are two duties which the shipowner is always presumed to undertake, and which are assumed to be unaffected and unqualified by the exceptions, unless a contrary intention is very clearly expressed by the terms of the contract. In the first place, he undertakes absolutely that the ship in which the goods are shipped is fit at the commencement of the voyage for the service to be performed. If during the voyage loss arises even from dangers of the seas or other excepted peril which would not have occurred if the vessel had been seaworthy and fit for the voyage at its commencement, the shipowner is not protected by the exceptions, and is liable for the loss. In the second place, there is an implied undertaking by the shipowner that all reasonable care will be taken by himself, his servants, and agents, safely to carry and deliver at their destination the goods received by him for carriage. Should loss or damage occur during the voyage, though the direct cause of such loss or damage be perils of the seas or other excepted peril, still the shipowner cannot claim exemption under the exceptions, if the shipper can prove that the loss or damage would not have occurred but for the negligence of the master, or crew, or other servants of the shipowner. The shipowner, in other words, is bound by himself and his servants to use all reasonable care to prevent loss by excepted perils as well as by any other cause.

It must not be supposed that even these primary obligations, which are introduced into every contract of affreightment not by words but by implication, may not be excluded by the express terms of the contract. It has now become *Express stipulations.* common form to stipulate that the shipowner shall not be liable for any loss arising from the negligence of his servants, or that he shall not be liable for loss by the excepted perils even when brought about by the negligence of his servants. And with regard to seaworthiness, it is not uncommon for the shipowner to stipulate that he shall not be responsible for loss arising even from the unseaworthiness of the ship on sailing, provided that due care has been taken by the owner, and his agents, and servants to make the ship seaworthy at the commencement of the voyage. There is indeed no rule of English law which prevents a shipowner from exempting himself by the terms of the bill of lading from liability for damage and loss of every kind, whether arising from unseaworthiness or any other cause whatsoever. In such a case the goods are carried at the owner's risk, and if he desires protection he must obtain it by insurance. In this respect the law of England permits greater freedom of contract than is allowed by the law of some other states. The owners, agents, and masters of vessels loading in the United States of America are forbidden by an Act of Congress, commonly called the Harter Act, passed in the year 1893, to insert in their contracts of affreightment any clause exempting the shipowner from liability for the negligence of his servants; but it is at the same time enacted that, provided all reasonable skill and care has been exercised by the shipowner to make the vessel seaworthy and fit for the voyage at its commencement, the shipowner shall not be liable for any loss caused by the negligence of the master or crew in the navigation of the vessel, or by perils of the sea or certain other causes set forth in the Act. It is now very usual to insert in the bills of lading of British vessels loading in the United States a reference to the Harter Act, incorporating its provisions so as to make them terms and conditions of the bill of lading.

The difficulty of construing the terms of bills of lading with regard to the excepted perils, often expressed in obscure and inexact language, has given rise to much litigation, the results of which are recorded in the Law Reports. Where such difficulties arise the question must be, What is the true and natural meaning of the language used by the parties? This question is not governed by the general rules which we have endeavoured to explain; but the words of the contract must always be considered with reference

to these rules, which are founded upon the well-established customs of merchants recognized and formulated by the courts of law.

(9) The bill of lading sometimes contains a clause as to the shipowner's *lien*. Without any express provision for it the shipowner has by the common law a lien for freight. If it is desired to give the shipowner a lien for *demurrage* (see below), or other charges, it must be expressly provided for. The *lien* is the right of the shipowner to retain the goods carried until payment has been made of the freight or the demurrage, or other charge for which a lien has been given. The lien may be waived, and is lost by delivery of the goods, or by any dealing with the consignee, which is inconsistent with a right of the shipowner to retain possession of the goods until payment has been made. The shipowner may preserve his lien by landing the goods and retaining them in his own warehouse, or by storing them in a public warehouse, subject to the conditions required by the Merchant Shipping Act, 1894.

Charter-parties.

Charter-parties are, as we have already explained, either for a voyage or for a period of time. (1) A charter-party for a voyage is a formal agreement made between the owner of the vessel and the charterers by which it is agreed that the vessel "being tight, staunch, and strong, and every way fitted for the voyage," shall load at a certain named place a full cargo either of goods of a specified description or of general merchandise, and being so loaded shall proceed with all possible despatch either to a specified place or to a place to be named at a specified port of call, and there deliver the cargo to the charterers or their assigns. There are clauses which provide for the amount of freight to be paid and the manner and time of payment; for the time, usually described as *lay days*, to be allowed for loading and discharging, and for the *demurrage* to be paid if the vessel is detained beyond the lay days; usually also a clause requiring "the cargo to be brought to and taken from alongside at merchant's risk and expense"; a clause that the master shall sign bills of lading for the cargo shipped either at the same rate of freight as is payable under the charter-party or very commonly at any rate of freight (but in this case with a stipulation that, if the total bill of lading freight is less than the total freight payable under the charter-party, the difference is to be paid by the charterers to the master before the sailing of the vessel); and there is usually what is called the *cesser clause*, by which the charterer's liability under the charter-party is to cease on shipment of the cargo, the shipowner taking a lien on the cargo for freight, dead freight, and demurrage. The charter-party is made subject to exceptions similar to those which are found in bills of lading. There are also usually clauses providing for the commissions to be paid to the brokers on signing the charter-party, the "address" commission to be paid to the agents for the vessel at the port of discharge, and other matters of detail. The clauses in charter-parties vary of course indefinitely, but the above is probably a sufficient outline of the ordinary form of a charter-party for a voyage.

What has been said with regard to bills of lading as to the voyage, the place of delivery, the exceptions and excepted perils, and the liability of the shipowner and his lien applies equally to charter-parties. It may be desirable to add a few words on *demurrage*, *dead freight*, and on the *cesser clause*.

Demurrage is, properly speaking, a fixed sum per day or per hour agreed to be paid by the charterer for any time during which the vessel is detained in loading or discharging over and above the time allowed, which is, as we have said, usually described as the *lay days*. Sometimes the number of days during which the vessel may be kept on demurrage at the agreed rate is fixed by the charter-party. If no demurrage is provided for by the charter-party, and the vessel is kept loading or discharging beyond the lay days, the shipowner is entitled to claim damages in respect of the loss which he has suffered by the detention of his ship; or, if the vessel is detained beyond the fixed number of demurrage days,

damages for detention will be recoverable. Sometimes there is no time fixed by the charter-party for loading or discharging. The obligation in such cases is to load or discharge with all despatch that is possible and reasonable in the circumstances; and if the loading or discharging is not done with such reasonable despatch, the shipowner will be entitled to claim damages for the detention of his ship. The rate of demurrage (if any) will generally be accepted as the measure of the damages for detention, but is not necessarily the true measure. When the claim is for detention and not demurrage the actual loss is recoverable, which may be more or may be less than the agreed rate of demurrage. The contract usually provides that Sundays and holidays shall be excepted in counting the lay days, but unless expressly stipulated this exception does not apply to the computation of the period of detention after the lay days have expired.

Dead freight is the name given to the amount of freight lost, and therefore recoverable by the shipowner from the charterer as damages if a full and complete cargo is not loaded in accordance with the terms of the charter-party.

The *cesser clause* has come into common use because very frequently the charterers are not personally interested in the cargo shipped. They may be agents merely, or they may have chartered the vessel as a speculation to make a profit upon the bill of lading freight. The effect of the clause is that when the charterers have shipped a full cargo they have fulfilled all their obligations, the shipowner discharging them from all further liability and taking instead a lien on the cargo for payment of all freight, demurrage, or dead freight that may be payable to him. It has become an established rule for the construction of the *cesser clause* that, if the language used will permit it, the *cesser* of liability is assumed to be coextensive only with the lien given to the shipowner; or, in other words, the charterers are released from those liabilities only for which a lien is given to the shipowner. The shipowner is further secured by the stipulation already referred to, that if the total freight payable under the bills of lading is less than the full chartered freight the difference shall be paid to the shipowner before the vessel sails. A difficulty which sometimes arises, notwithstanding these precautions, is that although an ample lien is given by the charter-party the terms of the bills of lading may be insufficient to preserve the same extensive lien as against the holder of the bills of lading. The shippers under the bills of lading, if they are not the charterers, are not liable for the chartered freight, but only for the bill of lading freight; and unless the bill of lading expressly reserves it, they are not subject to a lien for the chartered freight. The master may guard against this difficulty by refusing to sign bills of lading which do not preserve the shipowner's lien for his full chartered freight. But he is often put into a difficulty by a somewhat improvident clause in the charter-party requiring him to sign bills of lading *as presented*.

(2) A time charter-party is a contract between the shipowner and charterers, by which the shipowner agrees to let and the charterers to hire the vessel for a specified term for employment, either generally in any lawful trade or upon voyages within certain limits. A place is usually named at which the vessel is to be redelivered to the owners at the end of the term, and the freight is payable until such redelivery; the owner almost always pays the wages of the master and crew, and the charterers provide coals and pay port charges; the freight is usually fixed at a certain rate per gross register ton per month, and made payable monthly in advance, and provision is made for suspension of hire in certain cases if the vessel is disabled; the master, though he usually is and remains the servant of the owner, is required to obey the orders of the charterers as regards the employment of the vessel, they agreeing to indemnify the owners from all liability to which they may be exposed by the master signing bills of lading or otherwise complying with the orders of the charterers; and the contract is made subject to exceptions similar to those in bills of lading and voyage charter-parties. This is the general outline of the ordinary form of a time charter-party, but the forms and their clauses vary of course very much, according to the circumstances of each case.

It is apparent that under a time charter-party the shipowner to a large extent parts with the control of his ship, which is employed within certain limits accord-

ing to the wish and directions, and for the purposes and profit of, the charterers. But, as we have already explained at the beginning of this article, the shipowner continues in possession of his vessel by his servant the master, who remains responsible to his owner for the safety and proper navigation of the ship. The result of this, as has been already pointed out, is that the holder of a bill of lading signed by the master, if he has taken the bill of lading without knowledge of the terms of the time charter-party, may hold the owner responsible for the due performance of the contract signed by the master in the ordinary course of his duties, and within his ostensible authority as servant of the shipowner, although in fact in signing the bill of lading the master was acting as agent for and at the direction of the time charterer, and not the shipowner. In the language of the ordinary time charter-party the ship is *let* to the charterers; but there is no true demise, because, as we have pointed out, the vessel remains in the possession of the shipowner, the charterer enjoying the advantages and control of its employment. Where the possession of a ship is given up to a hirer, who appoints his own master and crew, different considerations apply; but though the instrument by which the ship is let may be called a charter-party, it is not truly a contract of affreightment.

There are certain rights and obligations arising out of the relationship of shipowner and cargo-owner in circumstances of extraordinary peril or urgency in the course of a voyage, which, though not strictly contractual, are well established by the custom of merchants and recognized by the law. It is obvious that, when a ship carrying a cargo is in the course of a voyage, the master to some extent represents the owners of both ship and cargo. In cases of emergency it may be necessary that the master should, without waiting for authority or instructions, incur expense or make sacrifices as agent not only of his employer, the shipowner, but also of the cargo-owner. Ship and cargo may be in peril, and it may be necessary for the safety of both to put into a port of refuge. There it may be necessary to repair the ship, and to land and warehouse, and afterwards reship the cargo. For these purposes

Customary rights.

the master will be obliged to incur expense, of which some part, such as the cost of repairing the ship, will be for the benefit of the shipowner; part, such as the warehousing expenses, will be for the benefit of the cargo-owner; and part, such as the port charges incurred in order to enter the port of refuge, are for the common benefit and safety of ship and cargo. Again, in a storm at sea, it may be necessary for the safety of ship and cargo to cut away a mast or to jettison, that is to say, throw overboard part of the cargo. In such a case the master, acting for the shipowner or cargo-owner, as the case may be, makes a sacrifice of part of the ship or part of the cargo, in either case for the purpose of saving ship and cargo from a danger common to both. Voluntary sacrifices so made and extraordinary expenses incurred for the common safety are called **GENERAL AVERAGE** (*g.v.*) sacrifices and expenses, and are made good to the person who has made the sacrifice or incurred the expense by a general average contribution, which is recoverable from the owners of the property saved in proportion to its value, or, in other words, each contributes ratably according to the benefit received. The law regulating the rights of the parties with regard to such contribution is called the Law of General Average. It must, however, be remembered that the owner of the cargo is entitled under the contract of affreightment to the ordinary service of the ship and crew for the safe carriage of the cargo to its destination, and the shipowner is bound to pay all ordinary expenses incurred for the purpose of the voyage. He must also bear all losses arising from damage to the ship by accidents. But when extraordinary expense has been incurred by the shipowner for the safety of the cargo, he can recover such expense from the owner of the cargo as a *special charge* on cargo; or when an extraordinary expense has been incurred or a voluntary sacrifice made by the shipowner to save the ship and cargo from a peril common to both, he may require the owner of cargo to contribute in *general average* to make good the loss.

GEOGRAPHY AND STATISTICS.

VERY much was contributed to our knowledge of Afghanistan during the last quarter of the 19th century. The Afghan war of 1878-80 afforded an opportunity for the extension of wide geographical surveys on a scientific basis; and this opportunity was afterwards repeated by the Russo-Afghan Boundary Commission of 1884-86. Since then much of the country on the immediate borders of India has been explored by the native employés of the Indian Survey during the progress of a series of minor expeditions; and the boundary delimitations which resulted from the agreement of November 1893 at Kabul, together with the frontier campaign of 1897-98, have finally reduced the geography of the whole borderland to practical shape. For the purposes of this article there will be included within the general term "Afghanistan" not only those districts which fall within the new political boundaries of the Kabul Government, but those states on the border, lying between Afghanistan and British India, whose status has lately been defined as "independent," and which are peopled either by Pathans or Afghans, speaking the same language and belonging to the same religious community as the Afghans of the Kabul kingdom.

River Basins.—Whilst, broadly speaking, the chief features of Afghan topography and hydrography were well enough known previously to the Afghan war of 1878, certain modifications in detail are to be noted in modern maps, and much supplementary information can now be added. It will be convenient to deal with Afghanistan under the natural divisions of its river basins rather than of the separate provinces included within its political boundaries. The following are the chief hydrographic divisions of the country—(1) the Kabul river and its tributaries; (2) the Indus affluents, which for the most part drain the independent provinces of the frontier; (3) the Oxus basin; (4) the basin of the Helmand; (5) the basin of the Hari Rud.

The Kabul river rises at the foot of the Unai pass, leading over the Sanglakh range, an offshoot of the Hindu Kush, towards Bamian and Afghan Turkestan. From its source to Kabul is only 45 miles as the crow flies, and the amount of water which the river carries is small and often insufficient for purposes of irrigation. Neither in volume nor in length is it to be compared with the Logar river, which joins it at a point less than half a mile east of Kabul. The Logar rises beyond Ghazni, amongst the slopes of the Gul Koh (14,200 feet) which overlooks the Ghazni plain from the west, and with minor affluents drains the rich valleys of Logar and Wardak for more than 100 miles ere it emerges from the gorges of the Shakh-i-Barant to join the Kabul

in the plain that stretches to Butkak. The valleys of the Logar are amongst the richest and most picturesque of Afghanistan. The united streams pass from the Kabul plain (6900 feet) through a precipitous gorge into the lower level of the Doaba to the north of the Kabul-Lataband road, and do not touch the road again till they pass Jalalabad. Meanwhile the volume of the river has been swelled at Doaba by the Tagao, which carries the drainage of the eastern slopes of the Hindu Kush from the head of the Panjshir, at the Khawák pass (11,640 feet) to the sources of the Ghorband, near the junction of the Hindu Kush with the Koh-i-Baba. Into the Tagao fall the rivers and streams of the Koh Daman north of Kabul as well as those of a considerable section of Kohistan, which forms Western Kafiristan; so that the Tagao affluents combined present probably a greater volume than the Kabul, at Doaba. Before reaching Jalalabad the Kabul receives another great contribution from the north in the united waters of the Alingar and the Alishang, which, under the former name, join in the Laghman plain. These two rivers between them drain all Central Kafiristan south of the Hindu Kush, and unite with the main channel of the Kabul in a broad clear stream which gives

little indication of its mountain origin. Very little is known about the catchment areas of these two rivers. It is a vast wilderness of mountains, the gates of which are jealously guarded by the Afghan Government; but the lower reaches of the Alingar pass through comparatively open plains, and are fringed with flourishing villages. The Laghman (or Lamghán) plain is important as indicating the ancient route from Kabul to India, which, instead of passing through Nangrahar and Jalalabad, followed the course of the Kabul river through this plain into the Kunar valley, and thence passed into Bajor, and was carried by one of several frontier passes into the plains of Peshawur. The Khaihar is a modern route, regarded as a main line of communication. The southern affluents of the Kabul river are insignificant; but two other great tributaries from the north—the Kunar, or river of Chitral, and the Swat (with its Panjkora affluent)—have been thoroughly examined. Only about one-third of the total length of the Kunar (270 miles from Lake Karambar on the Hindu Kush to Jalalabad) is within the limits of Afghanistan. The new political boundary crosses the valley at Arnawai, near the junction of the Bashgol river of Kafiristan with the Kunar. Above this point Chitral intervenes

SKETCH MAP OF AFGHANISTAN.

Walker & Cockerell sc.

between Afghanistan and the Gilgit province of Kashmir. Below it the eastern water-divide of the river shuts off Bajor. The extreme narrowness of the river basin is remarkable, there being no considerable affluent from either side except the Bashgol, whilst the craggy ranges which intervene between the stream and the Panjkora on the east (or again between the Panjkora and Swat rivers), although of enormous altitude (from 12,000 to 15,000 feet), stand on a base which averages less than 25 miles. Nearly due east of Chitral the culminating peaks overlooking the sources of the Panjkora to the south, and those of the Gilgit river to the east, rise to nearly 19,000 feet of altitude.

The Swat and Panjkora river basins belong to the Cis-Afghan independent territory, which was largely exploited during the recent north-western expeditions. Their main characteristics are those of the Kunar; but they rise far to the south of the sources of that river, the range which forms the southern water-divide of the Upper Gilgit basin enclosing those small tributaries amongst its southern spurs, which swell into big affluents ere they join these two historic streams. Much of the northern parts of their basins, including the districts of Darel and Tangir, immediately south of Gilgit, still remains to be explored. Within historic times much of the Lower Swat, Panjkora, and Kunar valleys was occupied by Kafir tribes, the limits of their occupation being traceable by the

total absence of those Buddhist archaeological remains which abound on all sides of the sphere of paganism.

That part of the basin of the Indus beyond the Kabul and its tributaries which appertains to Afghanistan is inconsiderable. It includes hardly more than the upper tributaries of the Gomul river, which rise in the plains between Waziristan and Ghazni, but the area of Cis-Afghan independent territory which is drained by the Indus is both extensive and politically important. Kanjut, the glacial region which gives birth to the Hunza river; the valleys of Yassin and of the Upper Gilgit; a long strip of territory adjoining the Indus—the region to which the name Kohistan is frequently given—all this independent territory forms a northern section of the Indus basin apart from the Kabul tributaries. Farther south the rivers of the frontier—the Kuram, the Tochi, the Gomul, and others between these, too many to enumerate—all drain downwards from the Afghan frontier through the independent strip of mountain barrier to effect (where the intervening sands permit) a junction with the Indus.

As all this country has been geographically surveyed, the outline of the disjointed hydrographical network which forms the western catchment of the Indus between Attok and the Gomul (where the political boundary of Baluchistan intervenes) may be best studied

on the maps of the Indian Survey. The frontier valleys belong to two distinct geological types. They are either deep, steep-sided valleys, with rapid streams carrying quantities of debris, or, where the upheaval of the river bed has been too rapid for the cutting-down action of the river, and the grade has been lessened, an alluvial plain has been formed, which affords a broad, open, and gently-rising ramp leading up to the Afghan plateau. Such are the valleys of the Kuram and the Tochi. The general flow of all these frontier affluents of the Indus from the Afghan plateau to the plains of the Derajat is directly across the axis of the minor frontier ranges, which lie packed in parallel lines of ridge and furrow, forming a series of grades, or steps, from the lower to the higher level. The streams rise on the plateau west of, and beyond, the prominent line of highest elevation, breaking straight through the hard sandstone or limestone ranges, and forming deep gorges where they pass; whilst their tributaries, joining almost at right angles in long narrow lateral valleys, wash the softer clays and shales from off the surface of the harder rocks, and carry down the debris to assist in grinding through the limestone barriers. The frontier hills between the Gomul and the Kuram present many instances of such narrow gateways to the Afghan highlands; to the south of the Gomul they form the most prominent type of opening into the hills.

Two important river basins of Afghanistan, belonging to that central system which has no connexion with the sea, have been examined, and many interesting facts connected with them remain to be recorded. The Hari Rud, or river of Herat, which loses itself in the Tejend oasis north of the Trans-Caspian Railway, and west of Merv, rises in the western slopes of the Koh-i-Baba, the mountain mass which abuts on, and closes, the Hindu Kush to the west of Kabul. It runs a remarkably straight course westward through a narrow trough from Daolatyar to Obek. This trough lies between the southern ridge of the great Central Afghan watershed, which holds the head-waters and sources of the Murghab on the north, and the narrow water-parting formed by the Band-i-Baián and Koh-i-Sufed on the south. From this latter divide the tributaries of the Farah Rud and other rivers of the Sistan basin take their rise. The deeply-eroded valley of the Hari Rud, filled in with the detritus washed down by periodical floods from the soft loess formations of sand and clay which enclose it, is of great fertility in its lower and wider reaches between Obek and Kulsán, 50 miles west of Herat; but its upper course is barren and sand-spread, winding amidst the bleak wind-swept uplands of the highest central elevations in Afghanistan. The most notable features about the Lower Hari Rud are the absolute exhaustion of its waters in the early summer seasons of irrigation, and the rapidity with which natural processes of denudation are lowering its bounding watersheds. Immediately north of Herat the central water-divide, which is locally known by the name of Siah Bubuk (but to which the general term Paropamisus has been given in order to preserve a historical designation which belongs more correctly to the Hindu Kush), is being reduced so rapidly to a final stage of rounded curves and gentle declivities that it is already possible to drive a wheeled carriage across it without any preliminary road-making. The sources of the Helmand, like those of the Hari Rud, lie in the recesses of the Koh-i-Baba to the west of Kabul, its infant stream parting the Unai pass from the Irak, the two chief passes on the well-known road from Kabul to Bamian. For fifty miles from its source its course is ascertained, but beyond that point for the next fifty no European has followed it. About the parallel of 33° N. lat. it enters the Zamindawar province, which lies to the north-west of Kandahar, and thenceforward it is a well-mapped river to its termination in the Lagoons, or Hamún, of Sistan. This great central depression, which is about 1700 feet above sea-level, also receives the waters of several northern affluents, of which the Harut, the Farah, and the Khash are the principal. They drain the highlands occupied by the Taimani section of the Chahar Aimák. About the upper affluents of the Farah lie the fertile valleys which surrounded Taiwara, the capital of the ancient kingdom of Ghor, and here the Taimani highlands culminate in peaks rising to a height of over 12,000 feet above sea-level. For 200 miles due east of Taiwara there stretches a region of barren highland desolation marked by peaks of 11,000 to 13,000 feet, the home of the Hazaras. Herein is enclosed a northern section of the valley of the Helmand, and in this portion of the valley is situated Ghizao, marking a great road from north to south. No other place of any significance is known in this region. All these northern affluents of the Sistan Hamúns partake more of the nature of highland rivers than the broad and comparatively placid Helmand. Throughout its great southern curve the Helmand shapes an even and solitary course, receiving no contributions from either side, through a valley which is exceedingly narrow, but fertile and green, and full of the last relics of departed townships belonging to that Kaiani kingdom which once centred on Kala Fath. From the Helmand, near its great bend northwards, a most extensive system of irrigation was

once devised, a system which watered hundreds of square miles of now barren plain to the west.

A noteworthy feature of the Sistan lagoon is that in times of excessive flood it overspreads a vast area of country, both to the north and south, shutting off the capital of Sistan (Nasirabad) from surrounding districts, and spreading through a channel southwards known as Shelag to another great depression called the Gaud-i-Zirreh. This great salt swamp is about 1000 feet lower in elevation and is situated so close to the Helmand as to leave but a few miles of broken ridge between. By that ridge all communication with Sistan must pass in time of flood. Sistan becomes a promontory connected with the desert south of the Helmand by that isthmus alone. Recent boundary proceedings have included it within the Amir's territory. The Afghan basin of the Oxus includes a part of the Pamirs and all Badakshan and Afghan Turkestan. Badakshan is drained by two main rivers—the Kokcha (or river of Faizabad) and the Khanabad, which takes its name from a town on its banks. Above the Kokcha junction the Oxus is a mountain-bred river, receiving no contributions of any importance from the Afghan side. Below the Khanabad the Oxus is a river of the plains; and as far as Khamiab, where it ceases to be the boundary of Afghanistan, no Afghan river of any importance reaches it. The Tashkurghan river, the Band-i-Amir or Balkh river, the Shiburghan, and the Andkhui, all start for it, bringing down snow-fed torrents from the Koh-i-Baba, and Band-i-Turkestan in Spring, and tailing off into the countless irrigation channels in the Balkh plain; but neither in winter nor in summer do any of them cross the fringe of sand desert that lies south of the Oxus river in cultivation. This appears to be due to the alteration of the plain levels by a gradual process of upheaval quite as much as to the absorption of the water-supply in irrigation. Where these rivers run into irrigation the plain is highly cultivated; but the Oxus itself is no longer utilized for agricultural purposes, except within a comparatively narrow fringe. This fringe is, however, of considerable local importance (see *Oxus*). On the western borders of Afghan Turkestan the Murghab river and the Hari Rud lose themselves in the Merv and Tejend oases. The Murghab starts from the Firozkhoi highlands (the northern scarp of which is defined by the Band-i-Turkestan), and, after traversing that plateau from east to west, it turns north through deeply-cut defiles to Bala Murghab and effects a final junction with the Kusk near Panjdeh. At Bala Murghab the valley is open, with the loess formation of the Chul bounding it on either hand. Beyond Panjdeh it emerges into the Yulatan desert.

Mountain Systems.—The dominant mountain system of Afghanistan is the Hindu Kush, and that extension westwards of its water-divide which is indicated by the Koh-i-Baba to the north-west of Kabul, and by the Firozkhoi plateau (Karjistan), which merges still farther to the west by gentle gradients into the Paropamisus, and which may be traced across the Hari Rud to Mashad.

The culminating peaks of the Koh-i-Baba overlooking the sources of the Hari Rud, the Helmand, the Kunduz, and the Kabul, very nearly reach 17,000 feet in height (Shah Fuladi, the highest, is 16,870), and from them to the south-west long spurs divide the upper tributaries of the Helmand, and separate its basin from that of the Farah Rud. These spurs retain a considerable altitude, for they are marked by peaks exceeding 11,000 feet. They sweep in a broad band of roughly parallel ranges to the south-west, preserving their general direction till they abut on the Great Registan desert to the west of Kandahar, where they terminate in a series of detached and broken anticlinals whose sides are swept by a sea of encroaching sand. The long, straight, level-backed ridges which divide the Argandab, the Tarnak, and Arghastan valleys, and flank the route from Kandahar to Ghazni, determining the direction of that route, are outliers of this system, which, geographically, includes the Khojak, or Khwaja Amran, range in Baluchistan.

North of the main water-divide of Afghanistan the broad synclinal plateau into which the Hindu Kush is merged is traversed by the gorges of the Saighan, Bamian, and Kamard tributaries of the Kunduz, and farther to the west by the Band-i-Amir or Balkh river. Between the debouchment of the Upper Murghab from the Firozkhoi uplands into the comparatively low level of the valley above Bala Murghab, extending eastwards in a nearly straight line to the upper sources of the Shiburghan stream, the Band-i-Turkestan range forms the northern ridge between the plateau and the sand formations of the Chul. It is a level, straight-backed line of sombre mountain ridge, from the crest of which, as from a wall, the extraordinary configuration of that immense loess deposit called the Chul can be seen, stretching away northwards to the Oxus—ridge upon ridge, wave upon wave, like a vast yellow-gray sea of storm-twisted billows. The Band-i-Turkestan anticlinal may be traced eastwards of the Balkh-ab

(the Band-i-Amir) within the folds of Kara Koh to the Kunduz, and beyond; but the Kara Koh does not mark the northern wall of the great plateau nor overlook the sands of the Oxus plain, as does the Band-i-Turkestan. Here there intervenes a second wide synclinal plateau, of which the northern edge is defined by the flat outlines of the Elburz to the south of Mazar-i-Sharif, and immediately at the foot of this range lie the alluvial flats of Mazar and Tashkurghan. Opposite Tashkurghan the Oxus plain narrows to a short 25 miles. On the south this great band of roughly undulating central plateau is bounded by the Koh-i-Baba, to the west of Kabul, and by the Hindu Kush to the north and north-east of that city. Thus the main routes from Kabul to Afghan Turkestan must cross either one or other of these ranges, and must traverse one or other of the terrific defiles which have been carved out of them by the upper tributaries of the rivers running northwards towards the Oxus. Probably in no country in the world are there gathered together within comparatively narrow limits so many clean-cut waterways, measuring thousands of feet in depth, affording such a stupendous system of narrow roadways through the hills.

After the Hindu Kush and the Turkestan ranges, that of the Safed Koh, which divides Ningrahar (or the valley of Jalalabad) from Kuram and the Afridi Tirah, is the most important, as it is the most impressive, in Afghanistan. But the general features of the Safed Koh have been sufficiently described already, and it only remains to illustrate its configuration in relation to the mountain systems about Kabul, and south of Peshawur. The highest peak of the Safed Koh, Sikaram, is 15,600 feet above sea-level. From this central dominating peak it falls gently towards the west, and gradually subsides in long spurs, reaching to within a few miles of Kabul and barring the road from Kabul to Ghazni. At a point which is not far east of the Kabul meridian an offshoot is directed southwards, which becomes the water-parting between the Kuram and the Logar at Shutargardan, and can be traced to a connexion with the great watershed of the frontier dividing the Indus basin from that of Helmand. This main watershed retains its high altitude far to the south. There are peaks measuring over 12,000 feet on the divide between the Tochi and the Ghazni plains. At the eastern extremity the Safed Koh splits and spreads into several branches. Between these branches are the Bazar valley; the Bara, which receives the Maidan drainage; the Khanke, and other lesser valleys. The Afridi Tirah is but an upland basin held within the arms of some of the minor Safed Koh spurs, which, from the peculiarity of its formation and its narrow drainage outlet, contains a vast depth of highly fertile alluvial soil.

Between the Safed Koh and the Gomul (where lies the official boundary of Baluchistan) the frontier mountain system is more irregular than it is south of that river, where an invariable system of close parallel flexures predominates. The first developments of this system are recognizable in the long straight ridges trending from north-east to south-west, which may be seen to the west of the peaks heading the Waziri group, forming the dividing line of the Indus basin. But this configuration is not so apparent in the Waziri hills or in those between the Kuram and the Kaitu, where the mountains are massed in more independent and isolated groups, facing steeply westwards and culminating on their western summits in peaks 11,600 feet above sea-level. But the same conformation of crumpled limestone ridges, overlaid with Tertiary deposits, which pervades all Afghanistan and Baluchistan, prevails also throughout Waziristan and determines its general outlines. The extension of a long ridge towards the Indus, which curves in a grand sweep northwards overlooking the river, introduces a welcome break into the monotonous regularity of frontier scenery. On this ridge is the frontier hill station of Sheikh Budin.

Geology.—So far as we know at present the geological history of Afghanistan differs widely from that of India. When, somewhere at the commencement of the Cretaceous period, the peninsula of India was connected by land with Madagascar and Southern Africa, all Afghanistan, Baluchistan, and Persia formed part of an area which was not perhaps continuously below sea-level, but which exhibited alternations of land and sea. The end of the Cretaceous period saw the commencement of a series of great earth movements ushered in by volcanic eruptions on a scale such as the earth has never since witnessed, which resulted in the upheaval of the Himalaya by a process of crushing and folding of the sedimentary rocks till marine fossils were forced to an altitude of 20,000 feet above the sea. It was not till the Tertiary age, and even late in that age, that much of the land area of Afghanistan was raised above the sea-level. Then the

ocean gradually retired into the great Central Asian depressions.

Everywhere there have been great and constant changes of level since that period, and the process of flexure and the formation of anticlinals traversing the northern districts of Afghanistan is a process which is still in action. So rapid has been the land elevation of Central Afghanistan that the erosive action of rivers has not been able to keep pace with that of upheaval; and the result all through Afghanistan (but specially marked in the great central highlands between Kabul and Herat) is the formation of those immensely deep gorges and defiles which are locally known as "daras." One of these, in the Astarab, to the south-east of Maimana, is but 30 yards wide, and is enclosed between perpendicular limestone cliffs 1500 feet high. Throughout Afghan Turkestan and Afghanistan the lowest beds belong to a marine Carboniferous era. These are overlaid by a long succession of strata, partly marine and partly fluvial, forming an unbroken series up to Jurassic times. On the upturned and denuded edges of these strata enormously thick beds of Cretaceous limestone rest unconformably; above these, again, marine and freshwater deposits are spread. Griesbach considers that the general outline of the land configuration has remained much the same since Pliocene times, and that the force which brought about the wrinkling of the older deposits still continues to add fold on fold. The highlands which shut off the Turkestan provinces from Southern Afghanistan have afforded the best opportunities for geological investigation, and, as might be expected from their geographical position, the general result of the examination of exposed sections leads to the identification of geological affinity with Himalayan, Indian, and Persian regions. The general configuration of the Turkestan highlands has been already indicated. Against the last great fold which terminates this mountain area northwards are ranged the Tertiaries and recent deposits. North of Maimana they form low undulating loess hills, in which most of the Band-i-Turkestan drainage is lost. This wide-spreading loess area, formed partly of wind-blown sand and partly of detritus from the mountains, is known as Chul, and merges into the great plains south of the Oxus river, a great part of which is covered with modern aerial deposits. Beneath this Chul formation the older beds of the outer and Turkestan ranges dip and pass to an irregular outcrop near the banks of the Oxus. Between the Oxus and the hills there has already been formed a rise or flexure in the ground, which extends more or less parallel to the northern edge of the hills, and, shutting in the cultivated area of the plains, arrests all tributaries seeking to effect a junction with the Oxus from the south, and leads to the formation of marshes and swamps. This appears to be the commencement of a new anticlinal which has altered the levels of the Balkh plain, and is indicative of those elevating processes which may have been effective within historic times in changing the climate and the agricultural prospects of this part of Central Asia. The Oxus itself is steadily encroaching on its right banks and depositing detritus on the left.

No fresh discoveries of minerals likely to be of high economic value to Afghanistan have been made of late years. Such as are known and worked at present have been worked from very ancient times, and their capacity is not likely to develop greatly under the Kabul Government. The most important feature in this connexion which was noted by the geologist of the Russo-Afghan Commission is the existence of vast coal beds in Northern Afghanistan.

There are no glaciers now to be found in Afghan Turkestan; but evidences of their recent existence are abundant. The great boulder bed terraces in some of the valleys of the northern slopes of the Ferozkhoi plateau are probably of glacial origin. In the mountains west of Kabul glaciers have retired, leaving the moraines perfectly undisturbed. They were probably cotemporary with the older alluvia.

Climate.—Over an area so large as Afghanistan, involving such varied conditions of geographical conformation, we find, as we might expect, a varied climatic record. Taking the highlands of the country as a whole there is no great difference between the mean temperature of Afghanistan and that of the lower Himalaya. Each may be placed at a point between 50° and 60° F. But the remarkable feature of Afghan climate (as also of the climate of Baluchistan) is its extreme range of temperature within limited periods. The least daily range in Northern Afghanistan is in the cold weather, the greatest in the hot. For seven months of the year (from May to November) this range exceeds 30° F. daily. The coldest month of the year is February, the mean minimum being 17° F.,

and the maximum 38°, in the northern Herat districts. Waves of intense cold occur, lasting for several days, and one may have to endure a cold of 12° below zero, rising to a maximum of 17° below freezing-point. The eastern reaches of the Hari Rud river are frozen hard in winter, rapids and all, and the people travel on it as on a road. On the other hand the summer temperature is exceedingly high, especially in the Oxus regions, where a shade maximum of 110° to 120° is not uncommon. Afghanistan lying outside monsoon influences, there are steadier weather indications than there are in India. The north-west blizzards which occur in winter and spring are the most notable feature, and their influence is clearly felt on the Indian frontier. The cold is then intense and the force of the wind cyclonic. It was a blizzard of this nature which proved so disastrous to the Afghan Boundary Commission in April 1885.

Political Boundaries.—In the realm of political geography, whilst no great changes have lately been effected in the political status of Afghanistan as an independent state subject to British suzerainty, more exact definition has been given to the extent of territory under Kabul rule; and the geographical limits of the Amir's responsibility have been more distinctly laid down by the delimitation of boundaries. These delimitations commenced with the Russo-Afghan Commission of 1885, and they concluded with the Mohmand expedition of 1897, at the close of a long series of disjointed efforts arising out of the agreement signed at Kabul in November 1893.

Commencing with the Persian border at Zulfikar on the Hari Rud river, the boundary between Afghanistan and Russia follows a line roughly parallel to the course of the Paropamisus, and about 35 miles to the north of it, till it strikes the Kushk river in Jamshidi territory at a point which was once known as Chahil Dukteran, but is now the Russian station of Kushk, and the terminus of a branch railway from Merve. The Russian Kushk is about 20 miles below the old Jamshidi settlement of the same name, itself about 15 miles north of the crest of the Paropamisus. The height of the Russian station is about 2000 feet above sea, and there is a rise of 4000 feet to the crest of the Paropamisus. From here to Herat (roughly 25 miles) the fall is about 3500 feet. From Kushk the boundary runs north-east, crossing the Murghab near Maruchak (which is an Afghan fortress), and thence passes north-east through the loess hills of the Chul, and the undulating deserts of the Aleli Turkmans, to the Oxus, leaving the valleys of Charshamba and of the Andkhui (to which it runs approximately parallel) within Afghan limits. These valleys denote the limits of cultivation in this direction. Throughout all this region the boundary is generally of an artificial character, marked by pillars, but it is here and there indicated by natural features forming local lines of water-parting or water-course. The boundary meets the Oxus at Khamiab at the western extremity of the cultivated district of Khwaja Salar, and from that point to the eastern end of Lake Victoria in the Pamirs the main channel of the Oxus river forms the northern limits of Afghanistan (see Oxus). Eastwards from Lake Victoria the frontier line was determined by the Pamir Boundary Commission in 1895. A part of the little Pamir is included in Afghan territory, but the boundary crosses this Pamir before the great bend northwards of the Aksu takes place, and, passing over a series of crags and untraversable mountain ridges, is lost on the Chinese frontier in the snowfields of Sarikol. Bending back westwards upon itself, the line of Afghan frontier now follows the water-parting of the Hindu Kush; and as the Hindu Kush absolutely overhangs the Oxus nearly opposite Ishkamish, it follows that, at this point, Afghanistan is about 10 miles wide. Thus a small and highly elevated portion of the State extends eastwards from its extreme north-eastern corner, and is attached to the great Afghan quadrilateral by the thin link of the Panja valley. These narrow limits (called Wakhan) include the lofty spurs of the northern flank of the Hindu Kush, an impassable barrier at this point, where the glacial passes reach 19,000 feet in altitude, and the enclosing peaks 24,000 feet. The backbone or main water-divide of the Hindu Kush continues to form the boundary between Afghanistan and those semi-independent native states which fringe Kashmir in this mountain region, until it reaches Kafirstan. From near the Dorah pass (14,800 feet), which connects Chitral with the Panja (or Oxus) river, a long, straight, snow-clad spur reaches southwards, which divides the Kafirstan valley of Bashgol

from that of Chitral, and this continues to denote the eastern limits of Afghanistan till it nearly touches the Chitral river opposite the village of Arnawai, 45 miles south of Chitral. Here the Bashgol and Chitral valleys unite and the boundary passes to the water-divide east of the Chitral river, after crossing it by a spur which leaves the insignificant Arnawai valley to the north; along this water-divide it extends to a point nearly opposite the quaint old town of Pashat in the Kunar valley (the Chitral river has become the Kunar in its course southwards), and then stretches away in an uneven and undefined line, dividing certain sections of the Mohmands from each other by hypothetical landmarks, till it strikes the Kabul river near Palosi. Thence following a course nearly due south, it reaches Lundi Kotal. From the abutment of the Hindu Kush on the Sarikol in the Pamir regions to Lundi Kotal, and indeed throughout its eastern and southern limits, the boundary of Afghanistan which we are describing does not part that country from British India, but from certain outlying independent frontier districts, all of which lie beyond the boundary which Britain inherited from the Sikhs, and which is still recognized as the limit of British India. Kanjut, Chitral, Bajor, the Mohmand districts, Swat, and Buner are all included in this fringe of quasi-independent territory, which, although the degree of independence enjoyed by it is of a different character altogether from that enjoyed by Afghanistan (being more immediately under British political control), has never yet been included within the red line. From the neighbourhood of Lundi Kotal the boundary is carried to the Safed Koh overlooking the Afridi Tirah, and then, rounding off the cultivated portions of the Kuram valley below the Peiwar, it crosses the Kaitu and passes to the upper reaches of the Tochi. Crossing these again, it is continued on the west of Waziristan, finally striking the Gomul river at Domandi. So far it has divided Afghanistan from the independent province of the Punjab. South of the Gomul it separates the interests of Afghanistan from those of Baluchistan. The Punjab independent provinces¹ are traversed by certain routes (the Khaibar, the Kuram, the Tochi, and the Gomul) which are held by British arms, and guarded by regulars or militia in British pay. At the western extremities of these routes India touches Afghanistan, and nowhere else. From Domandi (the junction of the Kunder river and the Gomul) the Afghan boundary marches with that of Baluchistan (see BALUCHISTAN). It is carried to the south-west on a line which is largely defined by the channels of the Kunder and the Kadanai to a point beyond the Sind Peshin terminal station of New Chaman, west of the Khojak range, and then drops southwards to Shorawak and Nushki. From Nushki it crosses the Helmand desert, touching the crest of a well-defined mountain watershed for a great part of the way, and, leaving Chagai to Baluchistan, it strikes nearly west to the Persian frontier, and joins it on the Koh-i-Malik Siyah mountain, south of Sistan. Two points of this part of the Afghan boundary are notable. It leaves some of the most fanatical of the Durani Afghan people on the Baluch side of the frontier in the Toba district, north of the Quetta-Chaman line of railway; and it passes 50 miles south of the Helmand river, enclosing within Afghanistan the only approach to Sistan from India which is available during the seasons of Helmand overflow. Between Afghanistan and Persia the boundary was defined by Sir F. Goldsmid's Commission in 1872 from the Malik-Siah-Koh to the Helmand Hamtins; beyond those lagoons to the northward it is still indefinite till it touches the district of Hashtadum in lat. 34° 15'. Here again a small section of about 40 miles has been delimited as far as the Hari Rud river at Toman Agha (some 12 miles below Kubsán), and from this point to Zulfekar the Hari Rud is itself the boundary.

Afghan Provinces.—Within the limits of this boundary the chief provinces of Afghanistan are those of Kabul, Zabul (or Kandahar), Herat, and Afghan Turkestan. The Kabul province mainly (for it is not possible to enter into details as regards these indefinite internal provincial boundaries) includes the Kabul basin, and Roh. Roh originally signified all the country of the Suliman and Khaibar hills so far as they are occupied by Pathans, *i.e.*, from Bajor on the north to Peshin and Sibi on the south, and from the Indus to Ghazni and the Khojak in the west. The word Roh means the same as Koh (a mountain), and the Roh mountaineers are the Rohilla of history. By the late boundary demarcation a part of Roh has become independent of Afghanistan, and the name might conveniently be applied to all that independent

¹ These provinces have been included in a political agency distinct from the Punjab since the above was written.

strip of territory which now intervenes as a buffer between British India and Afghanistan. Zabol includes Sistan, and, although well enough known to Afghans, the name has been superseded in colloquial English by Kandahar. It may be said to include the Helmand basin. Herat is, broadly speaking, the basin of the Hari Rud; and Afghan Turkestan includes the plains of Balkh and Badakshān.

Chief Cities.—The political and commercial activity of Afghanistan centres about the three cities of Kabul, Kandahar, and Herat, notices of which occur elsewhere in the *Ency. Brit.* Of other well-known cities of Afghanistan, Balkh (the mother of cities) and Ghazni are cities of the past, Mazar-i-Sharif is a religious, and Tashkurghan a commercial centre for the Oxus provinces of Afghan Turkestan. Maimana, Andkhui, Khanabad, and Faizabad are all places of note—walled towns, with local commandants, or governors, and busy, well-filled bazaars. There are, indeed, more widespread signs of general industrial activity in Afghan Turkestan than there are in the Herat and Kandahar provinces of Southern Afghanistan, where wide spaces exist which do not include a single town of importance. This is especially the case towards the western frontier, where, however, such local centres as Farah and Sabzawar, and such smaller industrial communities as Adraskand, Kin, and many other frontier villages, would undoubtedly develop into significance if encouraged by a railway.

Independent Tribes.—Collaterally with Afghanistan the political geography of that independent strip of territory which intervenes between the Afghan frontier and British India requires notice, for some of it formed part of the Afghan Durani empire, together with a large portion of the Punjab and Sind. It is only since 1896 that this independent "buffer" territory has become a political entity by the creation of the present Afghan boundary. Whether it long survives beyond the red line of the Punjab or not, assuredly it will never form part of Afghanistan again.

From the central water-divide of the Hindu Kush there reaches southwards a wide strip of mountainous country, formed by its elevated and intricate spurs, to the borders of the Peshawur plain. On the west this mountain district is bounded by Afghanistan; on the east it stretches beyond the Indus to the Khagan valley and Kashmir. This great wilderness of mountains includes the Chitral basin north of Arnawai; the valleys of Yasin, Karambar (or Ashkumán), and Hunza (the last known, as Kanjut), all forming part of the Gilgit basin; a considerable section of the Indus valley, in which lie the forts of Chilas and Takot; together with the peaks of Kohistan, Darel, and Tangir; the valley of Buner; the valleys of the Swat, Panjkora, Dir, Bajor, and a part of the Mohmand country. Some of these valleys are connected by political ties with Kashmir; others are quite independent (see GILGIT). It is nothing but a broad waste of mountains intersected by narrow rock-bound valleys, and traversed by routes which here and there are hardly distinguishable from the crudest goat-tracks. The southern part of this region, so full of geographical surprises and thorny political problems, is usually termed Yaghistan (the country of the independents) by the frontier people, and throughout these southern tracts the dominant race is that of the Afghan Yusufzai. Amongst this vast array of minor ranges, all of them offshoots of the Hindu Kush, the dividing ridge between the Gilgit drainage and the upper Chitral and Panjkora basins, which is called Shandur, is perhaps the most prominent feature. It shuts off Chitral from its base at Gilgit by a barrier which is over 12,000 feet in altitude. The alternative approach to Chitral from the south by Dir leads to no altitude greater than 10,500 feet—the height of the Lowarai pass leading from Dir to Kala Drosh. Yaghistan and the Chitral and Kanjut mountains separate British India effectually from the highlands of the Pamirs. Across that independent mountain waste no irruption into India has ever spread from the north. It forms a barrier which is practically as effective as that of Kafiristan on its western flank, and will continue to form a barrier so long as the glacier-bound passes and byways of the Hindu Kush are not improved into high-roads.

Immediately south of the Khaibar route the band of independent territory is continued by the Afridi uplands of the eastern

spurs of the Safed Koh. Then occurs the Kuram valley and the irregular mountain belt occupied by the Shiah Turis and Jajis. Here once more, as at Lundi Khana, British India touches Afghanistan on the Peshawur spurs, the valley of the Kuram being held by British levies. Next there intervenes a rough independent mountainous district drained by the Kaitu, between the Kuram and Tochi, where again the British line of occupation penetrates the frontier to the Afghan boundary. Beyond this, to the south, lies the Switzerland of the frontier, Waziristan forming a separate geographical and ethnographical division from the rest of the frontier. From the Khaibar to the Gomul the characteristics of the borderland are wide, flattish valleys, with comparatively gentle gradients filling in the open spaces between hills which are gradually being lowered by processes of denudation. There is little of that marked regularity of parallel flexures which is the prevailing feature south of the Gomul.

Ethnography.—The term Afghan really applies to one section only of the mixed conglomeration of nationalities which forms the people of Afghanistan, but this is the dominant section. The predominance of the Afghan in Afghanistan dates from the middle of the 18th century, when Ahmad Shah carved out Afghanistan from the previous conquests of Nadir Shah, and called it the Durani empire.

The Afghans claim to be *Ben-i-Israel*, and insist on their descent from the tribes who were carried away captive from Palestine to Media by Nebuchadnezzar. Yet they claim to be Pukhtan (or Pathán) in common with all other Pushto-speaking tribes, whom they do not admit to be Afghan. The bond of affinity between the various peoples who compose the Pathan community is simply the bond of a common language. All of them recognize a common code or unwritten law called Pukhtunwali, which appears to be similar in general character to the old Hebraic law, though modified by Mahomedan ordinances, and strangely similar in certain particulars to Rajput custom.

Since their national independence the Afghans of Afghanistan have styled themselves *Durani*. They are settled principally in the Kandahar country, extending into Sistan and to the borders of the Herat valley. Eastward they spread across the Afghan border into the Toba highlands north of the Khojak, where they are represented by Achakzai and Sadozai clans. They exist in the Kabul districts as Barakzai (the Amir's clan), and as Mahmudzai (Mohmands) and Yusufzai they occupy the hills north of the Kabul river, Bajor, Swat, Buner, and part of the Peshawur plains. All of the newly-demarcated independent provinces north of the Peshawur, and south of the Chitral and the Gilgit basin, are peopled with Afghans who are thus outside the frontier of Afghanistan.

After the Afghan the dominant people are the *Pukhtun*, or *Pathans*, who are represented by a variety of tribes, many of which are recognized as being of Indian origin. These non-Afghan Pathans occupy the hilly regions on the immediate British frontier. The Afridi, Jowaki, and Orakzai clans hold the highlands immediately south of the Khaibar and Peshawur. The Turis of the Kuram (of the Shiah persuasion), the Dawaris of Tochi, and the Waziris of Waziristan fill up the intervening Pathan hills north of the Gomul. In the Kohat district the Khat-tak and Bangash clans are Pathan, so that Pathans are found on both sides of the border. Pathans are probably the Pacyii or Pacyæ of Herodotus, who also mentions the Aprytæ or Afridi. In the utter absence of written history or of trustworthy genealogical evidence, the origin of most of the Pathan clans is likely ever to remain a mystery. It is enough that we can trace their existence in the regions they now occupy, or in contiguous districts, from the days of Herodotus. The immediate connexion of Britain with the Pathan of the Indian border makes him an important item in frontier ethnography; but he is not (within the limits of Afghanistan) to be considered as a political factor of anything like equal importance with the Ghilzai.

The *Ghilzai* is reckoned a Pathan, and he is connected with the Afghan; but he is of an entirely distinct origin, and he only claims ties of faith and affinity of language with other Afghan peoples—he does not admit kinship. The popular theory of the origin of the Ghilzai traces him to the Turkish tribe of Kilji, once occupying districts bordering the upper course of the Jexartes, and affirms that he was brought into Afghanistan by the Turk Sabaktegin in the 10th century of our era. However that may be, the Ghilzai clans now rank collectively as second to none in strength of military and commercial enterprise. They are a fine, manly race of people, and it is from some of their most influential clans (Suliman, Khel, Nasir, Khel, Kharotis, &c.) that the main body of povindah merchants is derived. These frontier commercial travellers trade between Ghazni and the plains of India, bringing down their heavily-laden khafi as at the commencement of the cold weather, and retiring

to the hills again ere the summer heat sets in. Thousands of them may be found during the winter months circulating through the farthest districts of the peninsula, where it not infrequently happens that they prove to be troublesome, if not dangerous, visitors. The Pathan, however, who finds his way across the sea to Australia is not of the Ghilzai tribe. He usually belongs to the Kakur section of Pachans, who occupy a large district in Baluchistan. Ghilzai chiefs take a lead in the politics of the country and possess much influence at the court of Kabul.

Underlying the predominant Afghan and Ghilzai elements in Afghan ethnography is the *Tajik*, representing the original Persian possessor of the soil, who still speaks his mother tongue. There are pure Persians in Afghanistan, such as the Kizzilbashes of Kabul, and the Naoshrwanis of Kharan; but the name Tajik appears to be applied only to an admixture of original Arab and Persian stock (such as the Dehwars), who are the slaves of the community—hewers of wood and drawers of water. Everywhere the Tajiks are the cultivators in rural districts, and the shopkeepers and clerks in the towns. The Tajik is as much the slave of the Pathan in Afghanistan as is the Hindki (whose origin is similar) in the plains of the Indus. Yet the Tajik population of the richly-cultivated districts north of Kabul proved themselves to be of good fighting material in the Afghan war of 1879-80, and the few Kizzilbashes that are to be found in the ranks of the Indian army are good soldiers.

Next in importance to the Tajik is the *Mongul* Hasara, who also speaks a dialect of Persian, and belongs to the Shia sect of Mahommedans. The Hazara are descendants of military colonists introduced by Chenghiz Khan; they occupy all the highlands of the upper Helmand valley, spreading through the country between Kabul and Herat, as well as into a strip of territory on the frontier slopes of the Hindu Kush north of Kabul. In the western provinces they are known as the Chahar Aimák (Hazaras, Jamshides, Taimanis, and Ferozkhois), and in other districts they are distinguished by the name of the territory they occupy. They are pure Monguls, intermixing with no other races (chiefly for the reason that no other races will intermix with them), preserving their language and their Mongul characteristics uninfluenced by their surroundings, having absolutely displaced the former occupants of the Hazarajat and Ghor. They make good soldiers and excellent pioneers. The Amir's companies of engineers are recruited from the Hazaras, and they form perhaps the most effective corps in his heterogeneous army.

In Afghan Turkestan we find the Tajik mixed with Turkish races—the Usbak and Turkman. Much interesting literature exists about the *Turkman*, the original Turk of Asia. By some ethnographers he is associated with the red-skinned Rajput in those early days when he was known to ancient geographers as Skyth. Others see in him an offshoot from the same original sources which developed the Teuton. He is at any rate non-Mongolian, and the old race hatred between Turk and Mongul is hardly less bitter now than it was in the days of Zahir-u-din Mahommed, otherwise called Babar, the royal Turk adventurer who founded that dynasty of Turkish emperors on the throne of Delhi which has been known to posterity as "Moghul." The chief Turkman tribes left to Afghan rule are the Alieli of the Daolatabad-Andkhui districts and the Ersari of the Khwaja Salar section of the Oxus frontier. Originally robbers and raiders, they are all of them now engaged in agricultural pursuits.

North of Kabul, in the Kohistan that borders Kafiristan, are certain races of mixed origin speaking Persian dialects, such as the Nimchas, Safis, &c., who fringe round the central mountain wilderness of Kafiristan, where are to be found secluded valleys and glens containing tribes and peoples (collectively called *Kafirs*), who speak dialects innumerable, and who were till lately independent of Afghanistan. Remnants of the ancient Baktria, flotsam and jetsam from old Greek colonies, intermingled with people of Indian origin forced upwards from the plains, are all represented in the Kafiristan wilderness. The ethnography of Kafiristan still requires elucidation. The well-known claim of the Kafir to be considered as of Greek extraction is partially supported by the late identification of a tribe of Kamdesh in lower Bashgol with the ancient Nicaeans of Arrian's history; and it seems probable that, with the progress of scientific investigation, recent theories of recognizable Greek elements in the population of certain districts south of Kabul will be fully sustained.

Roads and Passes.—Omitting the group of northern routes to India from Central Asia, which pass between Kashmir and Afghanistan through the defiles of Chitral and of the Indus (see HINDU KUSH), the highways of Afghanistan may be classed under two heads: (1) Foreign trade routes, and (2) Internal communications.

Of the many routes which cross the frontiers of Afghanistan the most important commercially are those which connect the Oxus regions and the Central Asian Khanates with Kabul, and

those which lead from Kabul, Ghazni, and Kandahar to the plains of India. Kabul is linked with Afghan Turkestan and Badakshan by three main lines of communication across the Koh-i-Baba and the Hindu Kush. One of these routes follows the Balkh river to its head from Tashkurghan, and then preserving a high general level of 8000 to 9000 feet, it passes over the water-divides separating the upper tributaries of the Kunduz river, and drops into the valley formed by another tributary, at Bamian. From Bamian it passes over the central mountain chain to Kabul either by the well-known passes of Irak (marking the water-divide of the Koh-i-Baba) and of Unai (marking the summit of the Sanglakh, a branch of the Hindu Kush), or else, turning eastwards, it crosses into the Ghorband valley by the Shibar, a pass which is considerably lower than the Irak and is very seldom snowbound. From the foot of the Unai pass it follows the Kabul river, and from the foot of the Shibar it follows the circuitous route which is offered by the drainage of the Ghorband valley, to Charikar, and thence southwards to Kabul. The main points on this route are Haibak, Bajgah, and Bamian. It is full of awkward grades and minor passes, but it does not maintain a high level generally, no pass (if the Shibar route be adopted) much exceeding 10,000 feet. That this has for centuries been regarded as the main route northward from Kabul, the Buddhist relics of Bamian and Haibak bear silent witness; but it may be doubted whether the Amir's talent for roadmaking has not opened out better alternative lines. One of his roads connects Haibak with the Ghorband valley by the Chahardar pass across the Hindu Kush. The pass is high (nearly 14,000 feet), but the road is excellently well laid out, and the route, which, south of Haibak, traverses a corner of the Ghor and Baghlan districts of Badakshan, is more direct. A third route also passes through Badakshan, and connects Kunduz with Charikar by the Khawák pass and Panjshir river. The latter joins the Ghorband close to Charikar. The Khawák (11,600 feet) is not a high pass; the grades are easy and the snowfall usually light. This high road is stated (on Afghan authority) to be kept open for kafilá traffic all the year round by the employment of forced labour for clearing snow. It is a recently-developed route and one of great importance to Kabul, both strategically and commercially. Routes passing westwards to the Afghan highlands through the mountain barriers of the frontier between Peshawur and the Gomul occur at intervals along the western border, and in this northern section of the north-west frontier they are all well marked. The Khaibar, Kuram, and Tochi are the best known, inasmuch as all these lines of advance into Afghanistan are held by British troops or Indian levies. But the lately-explored Bara valley route into the heart of the Afridi Tirah is not to be altogether overlooked, although it is not a trade route of any importance. The *Khaibar route* is described elsewhere. It should be noted that it was not in ancient times the main route of advance from Kabul to Peshawur. From Kabul the old route followed the Kabul river through the valley of Laghman (or Lamghan, as the Afghans call it) over a gentle water-parting into the Kunar valley, leaving Nangrahar and Jalalabad to the south. From the Kunar it crossed into Bajar by one of several open and comparatively easy passes, and from Bajar descended into India either by the Malakand or some other contiguous frontier gateway to the plains of Peshawur. The *Kuram route* involves the Peiwar and the Shutargardan passes (8600 and 10,800 feet respectively) across the southern extensions of the Safed Koh range, and has never been a great trade route, however suitable as an alternative military line of advance. Although trade at present does not extend largely between Afghanistan and India by the Tochi route, being locally confined to the valley and the districts at its head, yet this is the shortest and most direct route between Ghazni and the frontier, and in the palmy days of Ghazni raiding was the road by which the great robber Mahmud occasionally descended on to the Indus plains. Traces of his raiding and roadmaking are still visible, but it is certain that he made use of the more direct route to Peshawur far more frequently than he did of the Tochi. The exact nature of the connexion between the head of the Tochi and the Ghazni plain is still unknown to us. The *Gomul* is, and has ever been, the great central trade route between Afghanistan and India; and the position, which has lately been occupied by a British post at Wana, will do much to ensure its continued popularity. The Gomul involves no passes of any great difficulty, although it is impossible to follow the actual course of the river on account of the narrow defiles which have been cut through the recent conglomerate beds which flank the plains of the Indus. It has been carefully surveyed for a possible railway alignment; and an excellent road now connects Tank (at its foot) with the Zhob line of communications to Quetta, and with Wana on the southern flank of Waziristan. The Gomul route is of immense importance, both as a commercial and strategic line, and in both particulars is of far higher significance than either the Kuram or the Tochi.

Of the interior lines of communication, those which connect the great cities of Afghanistan, Herat, Kabul, and Kandahar, are obviously the most important. Between Kabul and Herat there is no "royal" road, the existing route passing over the frequently snowbound wastes that lie below the southern flank of the great Koh-i-Baba into the upper valleys of the Hari Rud tributaries. It is a waste, elevated, desolate region that the route traverses, and the road itself is only open at certain seasons of the year. Between Kabul and Kandahar exists the well-known and oft-traversed route by Ghazni and Kalat-i-Ghilzai. There is but one insignificant water-parting—or kotal—a little to the north of Ghazni; and the road, although unmade, may be considered equal to any road of its length in Europe for military purposes. Between Kandahar and Herat there is the recognized trade route which crosses the Helmand at Girishk and passes through Farah and Sabzawar. It includes about 360 miles of easy road, with spaces where water is scarce. There is not a pass of any great importance, nor a river of any great difficulty, to be encountered from end to end, but the route is flanked on the north between Kandahar and Girishk by the Zamindawar hills, containing the most truculent and fanatical clans of all the Southern Afghan tribes. Little need be said of the 65 miles of route between Kandahar and the Baluchistan frontier at New Chaman. It is on the whole a route across open plains and hard, stony "dasht"—a route which would offer no great difficulties to that railway extension from Chaman which has so long been contemplated. A very considerable trade now passes along this route to India, in spite of the almost prohibitive imposts of the Amir; but the trade does not follow the railway from New Chaman to the eastern foot of the Khojak. This part of the line is officially "boycotted" by the court at Kabul, and long strings of camels may still be seen from the train windows patiently treading their slow way over the Khojak pass to Kila Abdullah, whilst the train alongside them rapidly twists through the mountain tunnel into the Peshin valley.

Statistics.—No trustworthy statistics exist showing either present numbers or fluctuations in the population of Afghanistan. Within the Amir's dominions there are probably from four to five millions of people, and of these the vast majority are agriculturists.

The cultivators, including landowners, tenants, hired labourers, and slaves, represent the working population of the country, and as industrious and successful agriculturists they are unsurpassed in Asia. They have carried the art of irrigation to great perfection, and they utilize every acre of profitable soil. Certain Ghilzai clans are specially famous for their skill in the construction of the karez or underground water-channel. There are two harvests in most parts of Afghanistan; the first (consisting of cereals and some peas and beans) is reaped in summer, and the second in autumn, when rice, millet, arzun (*panicum halicum*), and Indian corn ripen. Vast quantities of fruit are grown and exported to India from both Kabul and Kandahar. *Assafostida* is indigenous to the western districts and also forms a considerable item of export.

The manufactures of the country have not developed much during recent years. Postins (sheepskin clothing) and the many varieties of camel and goat's hair-cloth which, under the name of "barak," "karak," &c., are manufactured in the northern districts, are still the chief local products of that part of Afghanistan. Herat and Kandahar are famous for their silks, although a large proportion of the manufactured silk found on the Herat market, as well as many of the felts, carpets, and embroideries, are brought from the Central Asian khanates. The district of Herat produces many of the smaller sorts of carpets ("galichas" or prayer-carpets), of excellent design and colour, the little town of Adraskand being especially famous for this industry; but they are not to be compared with the best products of Eastern Persia or of the Turkman districts about Panjdeh.

The nomadic Afghan tribes of the west are chiefly pastoral, and the wool of the southern Herat and Kandahar provinces is famous for its quality. In this direction, the late boundary settlements have undoubtedly led to a considerable development of local resources. A large quantity of wool, together with silk, dried fruit, madder, and *assafostida*, finds its way to India by the Kandahar route.

It is impossible to give accurate trade statistics, there being no trustworthy system of registration. The value of the imports from Kabul to India in 1892-93 was estimated at 221,000 Rx (or tens of rupees). In 1899 it was little over 217,000 Rx, the period of lowest intermediate depression being in 1897. These imports include horses, cattle, fruits, grain, wool, silk, hides, tobacco, drugs, and provisions (ghi, &c.). All this trade emanates from Kabul, there being no transit trade with Bokhara owing to the heavy dues levied by the Amir. The value of the exports from India to Kabul also shows great fluctuation. In the year 1892-3 it was registered at nearly 611,000 Rx. In 1894-5 it had sunk

to 274,000 Rx, and in 1899 it figured at 294,600 Rx. The chief items are cotton goods, sugar, and tea. In 1898-99 the imports from Kandahar to India were valued at 330,000 Rx, and the exports from India to Kandahar at about 264,000 Rx. Three-fourths of the exports consist of cotton goods, and three-eighths of the imports were raw wool. The balance of the imports was chiefly made up of dried fruits. Comparison with trade statistics of previous years on this side Afghanistan is difficult, owing to the inclusion of a large section of Baluchistan and Persia within the official "Kandahar" returns; but it does not appear that the value of the Western Afghanistan trade is much on the increase. The opening up of the route between Quetta and Sistan has doubtless affected a trade which was already seriously hampered by the Amir's short-sighted restrictions.

The Government of Afghanistan is monarchical, and succession to the throne is hereditary. There are five chief political divisions in the country—namely, Kabul, Turkestan, Herat, Kandahar, and Badakshan, each of which is ruled by a "naib" or governor, who is directly responsible to the Amir. Under the governors of provinces the nobles and kazis (or district judges) dispense justice much in the feudal fashion. Apart from the universal system of bribery and spoliation to which they give rise, feudal methods are more popular (and possibly more effective with a people like the Afghans) than high courts and the slow machinery of civil law would be. Swift even-handed justice is by no means rare in Afghanistan.

The Afghan army probably numbers nearly 50,000, distributed between the military centres of Herat, Kandahar, Kabul, Mazar-i-Sharif, Jalalabad, and Asmar, with detachments at frontier outposts on the side of India. The Amir's factories at Kabul for arms and ammunition are said to turn out about 20,000 cartridges and 15 rifles daily, with 2 guns per week; but it is probable that means are available for the acquisition of other military equipment than that manufactured in the country.

Financially, Afghanistan has never, since it first became a kingdom, been able to pay for its own government, public works, and army. There appears to be no inherent reason why this should be so. Whilst it can never (in the absence of any great mineral wealth) develop into a wealthy country, it can at least support its own population; and it would, but for the short-sighted trade policy of the Amir, certainly have risen, during the last twenty years of peace, to a position of respectable solvency. Its revenues (about which no trustworthy information is available) are subject to great fluctuations, and probably never exceed the value of one million sterling per annum. They fell in Sher Ali's time to £700,000. The original subsidy to the Amir from the Indian Government was fixed at 120,000 Rx per annum, but in 1893 in connexion with the boundary settlement it was increased to 180,000 Rx.

The religion of the country throughout is Mahommedan. Next to Turkey, Afghanistan is the most powerful Mahommedan kingdom in existence. The vast majority of Afghans are of the Sunni sect; but there are, in their midst, such powerful communities of Shiaks as the Hazaras of the central districts, the Kizzilbashes of Kabul, and the Toris, or Turis, of the Kuram border, nor is there between them that bitterness of sectarian animosity which is so marked a feature in India. The Kafirs of the mountainous region of Kafiristan alone are non-Mahommedan. They are sunk in a paganism which seems to embrace some faint reflexion of Greek mythology, Zoroastrian principles, and the tenets of Buddhism, originally gathered, no doubt, from the varied elements of their mixed extraction. Those contiguous Afghan tribes once included in Kafiristan, who have not so long ago been converted to the faith of Islam, are naturally the most fanatical and the most virulent upholders of the faith around them. In and about the centre of civilization at Kabul, instances of Ghazidom are comparatively rare. In the western provinces about Kandahar (amongst the Durani or true Afghans—the people who specially claim to be Ben-i-Israel), and especially in Zamindawar, the spirit of fanaticism runs high, and every other Afghan is a possible Ghazi—a man who has devoted his life to the extinction of other creeds.

Education is confined to most elementary principles in Afghanistan. Of schools or colleges for the purposes of a higher education befitting to the sons of noblemen and the more wealthy merchants, there is absolutely none; but the village school is an ever-present and very open spectacle to the passer-by. Here the younger boys are collected and instructed in the rudiments of reading, writing, and religious creed by the village mulla, or priest, who thereby acquires an early influence over the Afghan mind. The method of teaching is confined to that wearisome system of loud-voiced repetition which is so annoying a feature in Indian schools; and the Koran is, of course, the text-book in all forms of education. Every Afghan gentleman can read and speak Persian, which is the language of the court, and which is, indeed, more often heard in Kabul than Pushtu; but beyond this

acquisition (to which must certainly be added the arts and graces of good manners) education seems to be limited to the physical development of the youth by instruction in horsemanship and feats of skill. Such advanced education as exists in Afghanistan is centred in the priests and physicians; but the ignorance of both is almost phenomenal.

AUTHORITIES.—Since Afghanistan has been mapped and surveyed no comprehensive account of the country has been published. Apart from the survey reports and gazetteers of the Indian Government, the following are the chief recent sources of information:—KAYE. *History of the War in Afghanistan*, 1878.—MALLESON. *History of Afghanistan*. RECENT HISTORY.

In following the history of the course of affairs in Afghanistan during the 19th century, it should be remembered that the Saddozais and Bârakzais are two branches of the Durani tribe, which was raised to dominant power by its chief, Ahmed Khan, the founder of an Afghan kingdom under the Saddozai dynasty towards the end of the 18th century. His descendants had ruled, amid many vicissitudes, at Kabul, until in 1818 the assassination by the reigning Amir of his powerful minister, Fattah Khan Bârakzai, led to a revolt headed by the Bârakzai family, which ended in the expulsion of the Saddozai Shah Shujah, and the establishment at Kabul of Dost Mahommed, Fattah Khan's son; while Shah Shujah took refuge in the Punjab. By this time the political situation of Afghanistan had become materially affected by the consolidation of a formidable military dominion on its eastern frontier in the Punjab, under Ranjit Singh and his Sikh army. Ranjit Singh took advantage of the distracted condition of Afghanistan to seize Kashmir, and in 1823 he defeated the Afghans in a battle which gave him the suzerainty of the Peshawar province on the right bank of the Indus, though an Afghan chief was left to administer it. Ten years later Shah Shujah, the exiled Saddozai Amir, made a futile attempt to recover his kingdom. He was defeated by Dost Mahommed, when Ranjit Singh turned the confusion to his own account by seizing Peshawar and driving the Afghans back into their mountains.

At this point begins the continual interference of England and Russia in the affairs of Afghanistan, which has ever since exercised a dominant influence upon all subsequent events and transactions. It has not only transformed the situation of the ruling Amirs, but has also profoundly affected the Asiatic policy of the two European Governments. Shah Shujah's enterprise in 1833 had been supported by the co-operation of Ranjit Singh, and encouraged by the British Viceroy, Lord W. Bentinck. Although the ex-

pedition failed, the result was to excite jealousy of the British designs; and the Russian envoy at Tehran instigated the Shah of Persia to attack Herat, the important frontier fortress of north-western Afghanistan, which was then in the possession of an independent chief. In 1837, in spite of remonstrances from the British representative at Tehran, a Persian army besieged the city, but the appearance of British troops on the southern coast of Persia compelled the Persians to withdraw from Herat in 1838. The rivalry between England and Russia was now openly declared, so that each movement from one side was followed by a counter move on the Afghan chess-board from the other side. The British ministry had been seriously alarmed at the machinations of Russia and the attitude of Dost Mahommed at Kabul; and it was determined that the most effective means of securing their own interests within the country would be by assisting Shah Shujah to recover his sovereignty. A tripartite treaty was made between Ranjit Singh, the British Governor-General of India, and Shah Shujah; and a British army marched up the Bolan Pass to Kandahar, occupied that city, pushed on northwards to Ghazni, which was taken by assault, and entered Kabul in 1839. As Dost Mahommed had fled across the northern mountains, Shah Shujah was proclaimed king in his stead.

But this ill-planned and hazardous enterprise was fraught with the elements of inevitable failure. A ruler imposed upon a free people by foreign arms is always unpopular; he is unable to stand alone; and his foreign auxiliaries soon find themselves obliged to choose between remaining to uphold his power, or retiring with the probability that it will fall after their departure. The leading chiefs of Afghanistan perceived that the maintenance of Shah Shujah's rule by British troops would soon be fatal to their own power and position in the country, and probably to their national independence. They were insatiable in their demands for office and emolument, and when they discovered that the Shah, acting by the advice of the British envoy, was levying from among their tribesmen regiments to be directly under his control, they took care that the plan should fail. Without a regular revenue no effective administration could be organized; but the attempt to raise taxes showed that it might raise the people; so that for both men and money the Shah's government was still obliged to rely principally upon British aid. All these circumstances combined to render the new régime weak and unpopular; since there was no force at the ruler's command except foreign troops to put down disorder or to protect those who submitted; while the discontented nobles fomented disaffection and the inbred hatred of strangers in race and religion, among the general Afghan population. The result was that after two years' occupation of the country, in the vain hope of establishing a national government under Shah Shujah, the British found their own situation untenable; for the fierce and warlike tribes broke out into incessant revolt, until a serious insurrection at Kabul in the winter of 1841-42 compelled the British army to make an ignominious and disastrous retreat. The whole force was lost on the road between Kabul and Jalalabad; but Jalalabad was successfully defended by its British garrison, and General Nott held out at Kandahar until General Pollock's temporary re-occupation of Kabul in 1842 restored in some degree the military reputation of Great Britain. The British troops then completely evacuated the country. Dost Mahommed, who had been a state prisoner in India, was replaced on the Kabul throne; and the policy of intervention in Afghan affairs was suspended for nearly forty years.

It has been said that the declared object of this policy

British policy in Afghanistan.

had been to maintain the independence and integrity of Afghanistan, to secure the friendly alliance of its ruler, and thus to interpose a great barrier of mountainous country between the expanding power of Russia in Central Asia and the British dominion in India. After 1849, when the annexation of the Punjab had carried the Indian north-western frontier up to the skirts of the Afghan highlands, the corresponding advance of the Russians south-eastward along the Oxus river became of closer interest to the British, particularly when, in 1856, the Persians again attempted to take possession of Herat. Dost Mahommed now became the British ally, but on his death in 1863 the kingdom fell back into civil war, until his son Sher Ali had won his way to undisputed rulership in 1868. In the same year Bokhara became a dependency of Russia. To the British Government an attitude of non-intervention in Afghan affairs appeared in this situation to be no longer possible. A meeting between the Amir Sher Ali and the Viceroy of India (Lord Mayo) at Umballa in 1869 drew nearer the relations between the two governments; the Amir consolidated and began to centralize his power; and the establishment of a strong, friendly, and united Afghanistan became again the keynote of British policy beyond the north-western frontier of India.

When, therefore, the conquest of Khiva in 1873 by the Russians, and their gradual approach towards the Amir's northern border, had seriously alarmed Sher Ali, he applied for support to the British; and his disappointment at his failure to obtain distinct pledges of material assistance, and at Great Britain's refusal to endorse all his claims in a dispute with Persia over Seistan, so far estranged him from the British connexion that he began to entertain amicable overtures from the Russian authorities at Tashkend. In 1869 the Russian Government had assured Lord Clarendon that they regarded Afghanistan as completely outside the sphere of their influence; and in 1872 the boundary line of Afghanistan on the north-west had been settled between England and Russia so far eastward as Lake Victoria. Nevertheless the correspondence between Kabul and Tashkend continued, and as the Russians were now extending their dominion over all the region beyond Afghanistan on the north-west, the British Government determined, in 1876, once more to undertake active measures for securing their political ascendancy in that country. But the Amir, whose feelings of resentment had by no means abated, was now leaning toward Russia, though he mainly desired to hold the balance between two equally formidable rivals. The result of overtures made to him from India was that in 1877, when Lord Lytton, acting under direct instructions from Her Majesty's ministry, proposed to Sher Ali a treaty of alliance, Sher Ali showed himself very little disposed to welcome the offer; and upon his refusal to admit a British agent into Afghanistan the negotiations finally broke down.

In the course of the following year (1878) the Russian Government, to counteract the interference of England with their advance upon Constantinople, sent an envoy to Kabul empowered to make a treaty with the Amir. It was immediately notified to him from India that a British mission would be deputed to his capital, but he demurred to receiving it; and when the British envoy was turned back on the Afghan frontier hostilities were proclaimed by the Viceroy in November 1878, and the second Afghan war began. Sir Donald Stewart's force, marching up through Baluchistan by the Bolan Pass, entered Kandahar with little or no resistance; while another army passed through the Khyber Pass, and took up positions at Jalalabad and other

places on the direct road to Kabul. Another force under Sir Frederick Roberts marched up to the high passes leading out of Kuram into the interior of Afghanistan, defeated the Amir's troops at the Paiwar Kotal, and seized the Shutargardan Pass which commands a direct route to Kabul through the Logar valley. The Amir Sher Ali fled from his capital into the northern province, where he died at Mazâr-i-Sherif in February 1879. In the course of the next six months there was much desultory skirmishing between the tribes and the British troops, who defeated various attempts to dislodge them from the positions that had been taken up; but the sphere of British military operations was not materially extended. It was seen that the farther they advanced the more difficult would become their eventual retirement; and the problem was to find a successor to Sher Ali who could and would make terms with the British Government.

In the meantime Yakub Khan, one of Sher Ali's sons, had announced to Major Cavagnari, the political agent at the headquarters of the British army, that he had succeeded his father at Kabul. The negotiations that followed ended in the conclusion of a treaty in May 1879, by which Yakub Khan was recognized as Amir; certain outlying tracts of Afghanistan were transferred to the British Government; the Amir placed in their hands the entire control of his foreign relations, receiving in return a guarantee against foreign aggression; and the establishment of a British envoy at Kabul was at last conceded. By this convention the complete success of the British political and military operations seemed to have been attained; for whereas Sher Ali had made a treaty of alliance with, and had received an embassy from Russia, his son had now made an exclusive treaty with the British Government, and had agreed that a British envoy should reside permanently at his court. Yet it was just this final concession, the chief and original object of British policy, that proved speedily fatal to the whole settlement. For in September the envoy, Sir Louis Cavagnari, with his staff and escort, was massacred at Kabul, and the entire fabric of a friendly alliance went to pieces. A fresh expedition was instantly despatched across the Shutargardan Pass under Sir Frederick Roberts, who defeated the Afghans at Charasia near Kabul, and entered the city in October. Yakub Khan, who had surrendered, was sent to India; and the British army remained in military occupation of the district round Kabul until in December (1879) its communications with India were interrupted, and its position at the capital placed in serious jeopardy, by a general rising of the tribes. After they had been repulsed and put down, not without some hard fighting, Sir Donald Stewart, who had not quitted Kandahar, brought a force up by Ghazni to Kabul, overcoming some resistance on his way, and assumed the supreme command. Nevertheless the political situation was still embarrassing, for as the whole country beyond the range of British effective military control was masterless, it was undesirable to withdraw the troops before a government could be reconstructed which could stand without foreign support, and with which diplomatic relations of some kind might be arranged. The general position and prospect of political affairs in Afghanistan bore, indeed, an instructive resemblance to the situation just forty years earlier, in 1840, with the important differences that the Punjab and Sindh had since become British, and that communications between Kabul and India were this time secure.

Abdurrahman, the son of the late Amir Sher Ali's elder brother, had fought against Sher Ali in the war for succession to Dost Mahommed, had been driven beyond the

Cavagnari murdered and the war reopened.

Oxus, and had lived for ten years in exile with the Russians. In March 1880 he came back across the river, and began to establish himself in the northern province of Afghanistan. The Viceroy of India, Lord Lytton, on hearing of his reappearance, instructed the political authorities at Kabul to communicate with him. By skilful negotiations a meeting was arranged, and after pressing in vain for a treaty he was induced to assume charge of the country upon his recognition by the British as Amir, with the understanding that he should have no relations with other foreign powers, and with a formal assurance from the Viceroy of protection from foreign aggression, so long as he should unreservedly follow the advice of the British Government in regard to his external affairs. The province of Kandahar was severed from the Kabul dominion; and the Sirdar Sher Ali Khan, a member of the Barakzai family, was installed by the British representative as its independent ruler.

For the second time in the course of this war a conclusive settlement of Afghan affairs seemed now to have been attained; and again, as in 1879, it was immediately dissolved. In July 1880, a few days after the proclamation of Abdurrahman as Amir at Kabul, came news that Ayub Khan, Sher Ali's younger son, who had been holding Herat since his father's death, had marched upon Kandahar, had utterly defeated at Maiwand a British force that went out from Kandahar to oppose him, and was besieging that city. Sir Frederick Roberts at once set out from Kabul with 10,000 men to its relief, reached Kandahar after a rapid march of 313 miles, attacked and routed Ayub Khan's army on 1st September, and restored British authority in southern Afghanistan. As the British ministry had resolved to evacuate Kandahar, Sher Ali Khan, who saw that he could not stand alone, resigned and withdrew to India, and the Amir Abdurrahman was invited to take possession of the province. But when Ayub Khan, who had meanwhile retreated to Herat, heard that the British forces had retired, early in 1881, to India, he mustered a fresh army and again approached Kandahar. In June the fort of Girisk, on the Helmund, was seized by his adherents; the Amir's troops were defeated some days later in an engagement, and Ayub Khan took possession of Kandahar at the end of July. The Amir Abdurrahman, whose movements had hitherto been slow and uncertain, now acted with vigour and decision. He marched rapidly from Kabul at the head of a force, with which he encountered Ayub Khan under the walls of Kandahar, and routed his army on 22nd September, taking all his guns and equipage. Ayub Khan fled toward Herat, but as the place had meanwhile been occupied by one of the Amir's generals he took refuge in Persia. By this victory Abdurrahman's rulership was established.

In 1884 it was determined to resume the demarcation, by a joint commission of British and Russian officers, of the northern boundary of Afghanistan. The work went on with much difficulty and contention, until in March 1885, when the Amir was at Rawalpindi for a conference with the Viceroy of India, Lord Dufferin, the news came that at Panjdeh, a disputed place on the boundary held by the Afghans, the Russians had attacked and driven out with some loss the Amir's troops. For the moment the consequences seemed likely to be serious; but the affair was arranged diplomatically, and the demarcation proceeded up to a point near the Oxus river, beyond which the Commission were unable to settle an agreement.

During the ten years following his accession in 1880 Abdurrahman employed himself in extending and con-

solidating his dominion over the whole country. Some local revolts among the tribes were rigorously suppressed; and two attempts to upset his rulership—the first by Ayub Khan, who entered Afghanistan from Persia, the second and more dangerous one by Ishak Khan, the Amir's cousin, who rebelled against him in Afghan Turkestan—were defeated. By 1891 the Amir had enforced his supreme authority throughout Afghanistan more completely than any of his predecessors. In 1895 the Amir's troops entered Kafiristan, a wild mountainous tract on the north-east, inhabited by a peculiar race that had hitherto defied all efforts to subjugate them—and they have since been gradually reduced to submission. Meanwhile the delimitation of his northern frontier, up to the point where it meets Chinese territory on the east, has been completed and fixed by arrangements between the Governments of Russia and Great Britain; and the eastern border of the Afghan territory, towards India, has also been mapped out and partially laid down, in accordance with a convention between the two Governments. The Amir not only received a large annual subsidy of money from the British Government, but he also obtained considerable supplies of war material; and he moreover availed himself very freely of facilities that were given him for the importation at his own cost of arms through India. With these resources, and with the advantage of an assurance from the British Government that he would be aided against foreign aggression, he was able to establish an absolute military despotism inside his kingdom, by breaking down the power of the warlike tribes which held in check, up to his time, the personal autocracy of the Kabul rulers, and by organizing a regular army well furnished with European rifles and artillery. Taxation of all kinds was heavily increased, and systematically collected. The result was that whereas in former times the forces of an Afghan ruler consisted mainly of a militia, furnished by the chiefs of tribes who held land on condition of military service, and who stoutly resisted any attempt to commute this service for money payment, the Amir had at his command a large standing army, and disposed of a substantial revenue paid direct to his treasury. Abdurrahman executed or exiled all those whose political influence he saw reason to fear, or of whose disaffection he had the slightest suspicion; his administration was severe and his punishments were cruel; but undoubtedly he put down disorder, stopped the petty tyranny of local chiefs, and brought violent crime under some effective control in the districts. Travelling by the high roads is now comparatively safe; although it must be added that the excessive exactions of dues and customs have very seriously damaged the external trade. In short, Abdurrahman's reign produced an important political revolution, or reformation, in Afghanistan, which has risen from the condition of a country distracted by chronic civil wars, under rulers whose authority depended upon their power to hold down or conciliate fierce and semi-independent tribes in the outlying parts of the dominion, to the rank of a formidable military state governed autocratically. How long such a system will outlast the death of its founder in 1901, in the hands of his successor Habibulla, has yet to be seen; for in Asia a centralized administration and a standing army are institutions which depend for their maintenance entirely on the ruler's personal courage and capacity. Up to Abdurrahman's reign the strength of the Afghan nation lay in its warlike character, in the readiness of the tribes to combine for opposing and harassing an invader, and in the local independence of powerful clans or chiefs. Now that the power of the chiefs has been levelled down, and the fighting strength

Abdurrahman becomes Amir.

Abdurrahman's system of government.

Ayub Khan and Abdurrahman.

of the tribal groups has been dislocated, the defeat or mutiny of the regular forces may lead to widespread confusion in Afghanistan.

The extent of the territories subject to the rulers of Afghanistan has varied from time to time with political vicissitudes. Abdurrahman governed a kingdom strictly delimited between the possessions or dependencies of Russia, Persia, and India. **Afghan tribes on Indian frontier.** It should be mentioned, however, that the geographical boundaries of Afghanistan would include on the eastward all the highlands down to the skirts of the mountains that slope towards the Indian plains; for up to this line, and indeed beyond, the language, habits, and general character of the people are identical. But the frontier laid down in 1894 to mark the eastern limit of the Amir's jurisdiction, cut off from it a zone of tribal territory that had previously been for the most part under the nominal suzerainty of Kabul; though in reality it has always been a debateable land held by unruly and independent tribes. The zone thus interposed between British India and the Afghan rulership may be roughly described as stretching from the southern border of the Chitral state, along the whole north-western frontier of India southwards to the confines of Baluchistan. It is traversed by all the passes that lead out of the Afghan mountains into India; it is occupied at several points by British garrisons or levies in British pay; and it is inhabited by fierce, free, and warlike tribes, whose annals, so far as they have any, belong to the general history of the Afghan people. From time immemorial they have held the valleys and high ranges which overhang the main routes towards the low country; they have taken part in the incessant border wars and the great invasions of India, admitting allegiance to be due from them, as from all Afghans, to the chief ruler of their race, but acknowledging no master. Since 1849 the protection of the Indian borderland has necessitated sending into these hills frequent military expeditions, which have twice entangled the British in serious and prolonged fighting. In 1863 the

obstinate resistance made by the tribes to a large British force sent into their country was not overcome without great exertions; and in 1897-98 an insurrection of the tribes in the Swat valley was followed by a general rising of the Afridis, who destroyed a post of British levies in the Khyber Pass, and were only brought to terms after an arduous and harassing campaign. Since 1894, when the Amir of Kabul renounced all claim to jurisdiction over this region, the tribes of the outer hills and valleys on the Indian border have been gradually brought under the superintendence of the British Government by the location of posts inside their country, by enrolling tribal levies, and by other methods for strengthening control. Yet the management of these intractable and fanatic highlanders is still by far the most troublesome of the political and military difficulties that confront the Government along the whole external frontier of the Indian Empire.

Afiún Kara-Hissar, the popular name of Kara-hissar Sáhib, an important trade centre in Asia Minor, in the Brúsa viláyet. Called *Nicopolis* by Leo III. after his victory over the Arabs, in 740, its name was changed by the Seljúk Turks to *Kara-hissar*, "black castle." The town is in the centre of the opium, *afíun*, district, and is connected by railway with Smyrna, Konia, Angora, and Constantinople. Population, 18,000 (Moslems 13,000; Christians, 5000).

Afragola, a town in the province of Naples, Campania, Italy, 5 miles from Naples. It is on the steam tramway from Naples to Caivano. The principal industries are in straw hats, wine, and the manufacture of wooden articles of all sorts. There is a great annual fair on the second Sunday in May. Population about 20,000.

A F R I C A.

I. PHYSICAL GEOGRAPHY.

AFRICA, the largest of the three great southward projections from the main mass of the earth's surface, includes within its remarkably regular outline an area, according to the most recent computations, of 11,280,000 square miles, excluding the islands.

Form and area. Its main structural lines show both the east-to-west direction characteristic, at least in the eastern hemisphere, of the more northern parts of the world, and the north-to-south direction seen in the southern peninsulas. The continent is thus composed of two segments at right angles, the northern running from east to west, the southern from north to south, the subordinate lines corresponding in the main to these two directions.

Except quite in the north, the most striking feature in African geology is the great age of the fundamental structures and the absence of signs of recent disturbance of the crust leading to the elevation of folded mountain ranges. Both in the east and west of the meridional portion of the continent a broad zone parallel to the coast-line is composed mainly of ancient crystalline rocks (some of these showing signs of folding), on the flanks of which rocks of palæozoic age still remain in the position in which they were first deposited. In the east a band of gneissose and schistose

rocks, supposed to represent the primitive axis of the continent, has been traced at intervals for over half its length. Parallel with this and farther inland run broader belts of ancient rocks, forming in places wide granitic domes. In the west an almost continuous band of crystalline rocks—chiefly schists of varying character—accompanies the whole coast-line of the southern segment, as well as a large part of the southern margin of the western limb. Finally in the centre of the continent, near the meeting-line of the two segments, these ancient rocks seem to occur in lines intermediate between the two main directions. The wide basin between the eastern and western crystalline belts seems to be occupied largely by sedimentary strata, among which horizontally-bedded sandstones figure largely. Owing to the imperfection of the data, and in many cases to the absence of fossils, the age of the strata cannot yet be determined; but apart from recent fluvial and subaerial deposits, they seem to belong chiefly to the palæozoic or older mesozoic periods. Along the eastern main axis the crystalline rocks are largely overlaid with sheets of volcanic rocks, while numerous volcanoes, some long since extinct, some partially active, have thrust up piles of matter above them.

In Northern Africa the whole geologic structure dates from much more recent times. The most important feature here is the existence of a folded mountain range

of comparatively recent date, which runs from east to west parallel to the northern coast. This range—the Atlas—belongs to the European system both in its direction and in its constituent formations. **North and South Africa.** Archæan rocks play quite a subordinate part, while a regular series of stratified formations, from palæozoic to tertiary, most of which have equally experienced the effects of folding, constitute the greater part of the range. Of these the mesozoic—particularly the cretaceous—cover the largest area, while tertiary strata occur chiefly in narrow bands near the coast. The eastern half of North Africa contains large expanses both of tertiary formations and of cretaceous. The extreme south of the continent is marked by the large extent of mesozoic formations (trias, &c.), in addition to older rocks.

The mean elevation of Africa has been variously estimated at from 1962 feet (Heiderich) to 2133 (Wagner)

and may thus be considered to approximate closely to 2000 feet, which is roughly the elevation of both North and South America, but is considerably less than that of Asia (3117 feet). In contrast with the other continents it is marked by the comparatively small area both of very high and of very low ground, lowlands under 600 feet occupying an unusually small part of the surface; while not only are the highest elevations inferior to those of Asia and South America, but the area of land, over 10,000 feet, is also quite insignificant, being represented almost entirely by individual peaks and mountain ranges. Moderately elevated tablelands are thus the characteristic feature of the continent, though the surface of these is broken by higher peaks and ridges. As a general rule, the greater elevations lie to the east, and south, while a progressive diminution in altitude towards the west and north is observable. Apart from the lowlands and the Atlas range, the continent may be divided into two regions of higher and lower plateaux, the dividing line (somewhat concave to the north-west) running from the middle of the Red Sea to about 6° S. on the west coast. We thus obtain the following four main divisions of the continent:—(1) The coastal plains—often fringed seawards by mangrove swamps—never stretching far from the coast, except on the lower courses of streams. Recent alluvial flats are found chiefly in the delta of the more important rivers. Elsewhere the coast lowlands merely form the lowest steps of the system of terraces which constitutes the ascent to the inner plateaux. (2) The Atlas range, which, orographically as geologically, is distinct from the rest of the continent, being unconnected with any other area of high ground, but divided off on the south by a depressed area in places below sea-level. (3) The high southern and eastern plateaux, rarely falling below a height of 2000 feet, and having a mean elevation of about 3500. (4) The north and west African plains, bordered and traversed by bands of higher ground, but generally below 2000 feet.

The two last divisions may be again subdivided. Thus the high plateaux include:—(a) the South African plateau as far as about 12° S., bounded on all sides by bands of high ground which fall steeply to the coasts. On this account South Africa has a general resemblance to an inverted saucer. The bounding ridges belong, as a rule, to the crystalline axes of the continent, but in the south-east, where they attain their maximum elevation in the Drakensberg range, the ancient rocks are overlaid by extensive beds of permian and trias. Quite in the south the plateau rim is formed by three parallel steps with level ground between them. In the north the interior basin is demarcated merely by a strip of plateau somewhat more elevated than the rest of the surface. The South African plateau is connected towards

the north-east with (b) the East African plateau, with probably a slightly greater average elevation, and marked by some distinct features. It is formed by a widening out of the eastern axis of high ground, which becomes subdivided into a number of zones running north and south and consisting in turn of ranges, tablelands, and depressions. A wide area of granite and gneiss runs down the centre, forming in part a rolling plain, while the more elevated ridges are composed chiefly of schists, quartzites, and stratified rocks. The most striking feature is the existence of two great lines of depression, due largely to the subsidence of whole segments of the earth's crust, the lowest parts of which are occupied by vast lakes. Towards the south the two lines converge and we find only one great valley (occupied by Lake Nyasa), the southern part of which is less distinctly due to rifting and subsidence than the rest of the system. Farther north the western depression, sometimes known as the Central African trough, is occupied for more than half its length by water, forming the four lakes of Tanganyika, Kivu, Albert Edward, and Albert, the first-named over 400 miles long and the longest fresh-water lake in the world. Associated with these great valleys are a number of volcanic peaks, the greatest of which occur on a meridional line east of the eastern trough. The eastern depression, known as the East African trough or rift-valley, contains much smaller lakes, many of them brackish and without outlet, the only one comparable to those of the western trough being Lake Rudolf, or Basso Norok. Towards the northern end are Kilimanjaro—with its two peaks Kibo and Mawenzi, the former (according to Dr. Hans Meyer's latest measurement) 19,430 feet, and probably the culminating point of the whole continent—and Kenya (17,180 feet). Hardly less important is the Ruwenzori range (probably over 18,000 feet), which lies east of the western trough. Other volcanic peaks rise from the floor of the valleys, Kirunga, north of Lake Kivu, being still partially active. (c) The third division of the higher region of Africa is formed by the Abyssinian highlands, a rugged mass of mountains forming the largest continuous area of its altitude in the whole continent, little of its surface falling below 5000 feet, while the summits reach heights of 15,000 to 16,000 feet. This block of country lies just off the line of the great East African trough, the northern continuation of which passes along its eastern escarpment as it runs up to join the Red Sea. There is, however, in the centre a circular basin occupied by Lake Tsana. The basis of the region is a mass of ancient crystalline rocks which have been furrowed by deep valleys under the influence of denudation. They are surmounted, especially towards the south, by a large area of newer volcanic rocks, which have once covered the surface in continuous sheets, while the north-western margin is overlaid by sedimentary strata of Jurassic age.

The lower north-western half of Africa, though the greater part of its area is below 2000 feet, is traversed by bands of higher ground which run off from the higher lands to the south. Both in the east and west the bordering highlands are continued as strips of plateau parallel to the coast, the Abyssinian mountains being continued northwards along the Red Sea coast by a series of ridges reaching in places a height of 7000 feet. In the west the zone of high land is broader but somewhat lower. The most mountainous districts lie inland from the head of the Gulf of Guinea (Adamawa, &c.), where heights of 6000 to 8000 feet are reached. Exactly at the head of the gulf the great peak of the Cameroon, on a line of volcanic action continued by the islands to the south-west, has a height, according to the measurements of Dr. Preuss, of 13,370 feet, while Clarence Peak,

in the first of the line of islands, rises to over 9000. Towards the extreme west the Futa Jallon highlands form an important diverging point of rivers, but beyond this, as far as the Atlas chain, the elevated rim of the continent is almost wanting. The intervening space between the east and west coast highlands is divided into separate basins by other bands of high ground, one of which runs nearly centrally through North Africa in a line corresponding roughly with the curved axis of the continent as a whole. The best marked of the basins so formed occupies a circular area in West Africa bisected by the equator, once probably the site of an inland sea and now largely covered by recent alluvium.

The following table gives the approximate altitudes of the most important features of the continent:—

TABLE OF ALTITUDES.

MOUNTAINS—	FEET.	LAKES (<i>continued</i>)—	FEET.
Aiashi (Atlas)	14,000 ¹	Kivu	4900

From the outer margin of the African plateaux a large number of streams run down to the sea with comparatively short courses, while the rivers of the first class flow for long distances on the interior highlands before breaking through the outer ranges. The main drainage of the continent is to the north and west, or towards the basin of the Atlantic Ocean. The high lake plateau of East Africa contains the headwaters of the Nile and Congo; the former the longest, the latter the largest river of the continent. The southern branch of the Nile receives its chief supplies from the mountainous region adjoining the Central African trough in the neighbourhood of the equator. Thence streams pour east to the Victoria Nyanza, the largest African lake, and west and north to the Albert Edward and Albert Nyanzas, to the latter of which the effluents of the other two lakes add their waters. Issuing from it the Nile flows north, and between 7° and 10° N. traverses a vast marshy level, during which its course is liable to blocking by floating vegetation. After receiving the Bahr-el-Ghazal from the west and the Sobat, Blue (more correctly, Black) Nile, and Atbara from the Abyssinian highlands, it crosses the great desert and enters the Mediterranean by a vast delta. The most remote head-stream of the Congo is the Chambezi, which flows south-west into the marshy Lake Bangweulu, afterwards turning north through Lake Mweru and descending to the forest-clad basin of west equatorial Africa. Traversing this in a majestic northward curve and receiving vast supplies of water from many great tributaries, it finally turns south-west and cuts a way to the Atlantic Ocean through the western highlands. North of the Congo basin and separated from it by a broad undulation of the

surface is the interior basin of Lake Chad—a flat-shored lake filled principally by the Shari coming from the south-east. West of this is the basin of the Niger, the third river of Africa, which, though flowing to the Atlantic, has its principal source in the far west, and reverses the direction of flow exhibited by the Nile and Congo. An important branch, however—the Benue—comes from the south-east. These four river-basins occupy the greater part of the lower plateaux of North and West Africa, the remainder consisting of arid regions watered only by intermittent streams which do not reach the sea. Of the remaining rivers of the Atlantic basin the Orange, in the extreme south, brings the drainage from the Drakensberg on the opposite side of the continent, while the Kunene, Kwanza, Ogowe, and Sanaga drain the west coast highlands of the southern limb; the Volta, Komoe, Bandama, Gambia, and Senegal those of the western limb.

Of the rivers flowing to the Indian Ocean the only one draining any large part of the interior plateaux is the Zambezi, the western branches of which come from the neighbourhood of the west coast. Recent explorations have shown that the most remote head-stream is the Liba, which, rising midway across the continent, flows west and south before assuming the eastward direction of the lower river. All the largest tributaries, including the Shiré, the outflow of Lake Nyasa, flow down the southern slopes of the band of high ground which stretches across the continent in 10° to 12° S. In the south-west the Zambezi system interlaces with that of the Tawkhe (or Tioghe), from which it at times receives surplus water. The rest of the water of the Tawkhe is lost in a system of swamps and salt pans which formerly centred in Lake Ngami, now dried up. Farther south the Limpopo drains a portion of the interior plateau but breaks through the bounding highlands on the side of the continent nearest its source. The Rovuma, Rufiji, Tana, Juba, and Webi Shebeli principally drain the outer slopes of the East African highlands, the last-named losing itself in the sands in close proximity to the sea. Lastly, between the basins of the Atlantic and Indian Oceans, there is an area of inland drainage along the centre of the East African plateau, directed chiefly into the lakes in the great rift-valley. The largest river is the Omo, which, fed by the rains of the Abyssinian highlands, carries down a large body of water into Lake Rudolf.

The latest calculations of the areas of African drainage systems, made by Dr A. Bludau (*Petermanns Mitteilungen*, 43, 1897, pp. 184-6) gives the following general results:—

Basin of the Atlantic	4,070,000 sq. miles.
Do. Mediterranean	1,680,000 "
Do. Indian Ocean	2,086,000 "
Inland drainage area	3,452,000 "

The areas of individual river-basins are:—

Congo	1,425,000 sq. miles.
Nile	1,082,000 "
Niger	808,000 ² "
Zambezi	513,500 "
Lake Chad	394,000 "
Orange	370,500 ² "
Do. (actual drainage area)	172,500 "

The area of the Congo basin is greater than that of any other river except the Amazon, while the African inland drainage area is greater than that of any continent but Asia, in which the same area is 4,900,000 sq. miles.

The principal African lakes have been alluded to in the description of the East African plateau, but some of the phenomena connected with them may be spoken of more particularly here. As a rule the lakes

¹ Estimated.

² Including waterless tracts naturally belonging to basin.

which occupy portions of the great rift-valleys have steep sides and are very deep. This is the case with the two largest of the type, Tanganyika and Nyasa, the latter of which was found in 1899 to have a depth of 430 fathoms. Others, however, are shallow, and hardly reach the steep sides of the valleys in the dry season. Such are lake Rukwa, in a subsidiary depression north of Lake Nyasa, and Eiassi and Manyara, in the system of the eastern rift-valley. Lakes of the broad type, such as the Victoria Nyanza, are probably of intermediate depth. Apart from the seasonal variations of level, most of the lakes show periodic fluctuations, while some have supposed that a progressive desiccation of the whole region is traceable, tending to the ultimate disappearance of the lakes. Such

SKETCH MAP OF THE LAKE REGION OF AFRICA.

on the contrary, risen in level, Nyasa having been unusually high in 1896 and Rudolf in 1896-98; so that, if the fluctuations are due to variations of rainfall, these do not affect the whole lake region simultaneously in the same direction. In the case of the Victoria Nyanza a variation to the extent of 5 feet has been thought to recur in periods of eighteen to twenty-five years. Since 1896 records of the seasonal variations have been kept at stations north of the lake; the maximum in the year having been so far about 15 inches. They may be accounted for in part by the action of winds. Besides the East African lakes the principal are:—Lake Chad, in the northern area of inland drainage; Bangweulu and Mweru, traversed by the head-stream of the Congo; and Leopold II. and Mantumba, within the great bend of that river. All, except possibly Mweru, are more or less shallow. The altitudes of the African lakes have already been stated.

Divergent opinions have been held as to the mode of origin of the Central African lakes, especially Tanganyika, which some geologists have considered to represent an old arm of the sea, dating from a time when the whole central Congo basin was under water; others holding that the lake water has accumulated in a depression caused by subsidence. The former view

derives some support from the existence in the lake of organisms of a decidedly marine type, the investigation of which has been the work of Mr J. E. S. Moore. They include a jelly-fish, molluscs, prawns, crabs, &c., and form an isolated group found in no other of the African lakes. M. J. Cornet, a Belgian geologist, has expressed a doubt whether these organisms furnish evidence of a former connexion of Tanganyika with the sea.

Lying almost entirely within the tropics, Africa does not show excessive variations of temperature. Great summer heat is experienced in the lower plains of North Africa, removed by the great width of the continent from the influence of the ocean, and here too the contrast between day and night, and between summer and winter, is greatest. Farther south, the heat is to some extent modified by the moisture brought from the ocean, and by the greater elevation of a large part of the surface, especially in East Africa, where the range of temperature is also wider than in the western basin. In the extreme north and south the climate is a warm temperate one. The most important climatic differences are due to variations in the amount of precipitation. The wide heated plains of North Africa, and in a lesser degree a corresponding zone of latitude in the south, have an exceedingly scanty rainfall, the winds which blow over them from the ocean losing part of their moisture as they pass over the outer highlands, and becoming constantly drier owing to the heating effects of the burning soil of the interior; while the scarcity of mountain ranges in the more central parts likewise tends to prevent condensation. In the inter-tropical zone of summer precipitation, this is greatest when the sun is vertical or soon after. It is therefore greatest of all near the equator, where the sun is twice vertical, and less in the direction of both tropics. The rainfall zones are, however, somewhat deflected from a due west-to-east direction, the drier northern conditions extending southwards along the east coast, and those of the south northwards along the west. Within the equatorial zone certain areas, especially on the shores of the Gulf of Guinea and in the Upper Nile basin, have an intensified rainfall, but this rarely approaches that of the rainiest regions of the world. The rainiest district in all Africa, and (in the present state of knowledge) the second rainiest in the world, is a little west of Mt Cameroon, where at the Debnunja station the following results have been recorded:—

1895	353.04 inches	} Mean . 372.40 inches.
1896	384.96 "	
1897	372.72 "	
1898	379.20 "	

as compared with a mean of 475 inches at Cherrapunji, in Assam. The two distinct rainy seasons of the equatorial zone, where the sun is vertical at half-yearly intervals, become gradually merged into one in the direction of the tropics, where the sun is overhead but once. The question of a progressive desiccation of the continent has been touched upon in speaking of the lakes.

While the climate of the north and south, especially the latter, is eminently healthy, and even the intensely heated Sahara is salubrious by reason of its dryness, the tropical zone as a whole is the most unhealthy portion of the world. This is especially the case in the lower and moister regions, such as the west coast, where malarial fever is very prevalent and deadly; the most unfavourable factors being humidity with absence of climatic variation (daily or seasonal). The higher plateaux, where not only is the average temperature lower, but such variations are more extensive, are more healthy; but even here, with the exception of a few specially favoured localities, Europeans find it difficult to maintain their health permanently. Opinions still differ

Origin of lakes.

as to the possibility of the acclimatization of white men in Africa, some holding that acclimatization can only be the result of a gradual process extending through many generations, while others believe that with improved knowledge the diseases of Africa and other tropical countries can be successfully dealt with. (On this subject see article by Dr Sambon in *Geographical Journal*, vol. xii. p. 589.) It is believed by the latter school that the malarial germs are propagated by the agency of mosquitos, and during 1899 the discovery of the particular species to which infection is due in West Africa was claimed to be made by Major Ross. Hopes are entertained that suitable measures may lead to its destruction.

Meteorological Observations.

During the last decade of the 19th century a great impetus was given to the record of meteorological data at stations in Central Africa, and our scanty knowledge with respect to that region has already received important additions. The following tables summarize some of the latest results:—

The first of these tables gives the climatological phenomena at a station in the humid and equable region of the west coast. The dry season is reduced to a minimum, occurring at the time when the sun is at its greatest southward declination. The relative humidity is high and the temperature shows small seasonal variations. The second table, relating to a station on the east coast, likewise shows small variations of temperature, but a relatively small rainfall, divided chiefly between two distinct rainy seasons. The third, the much greater temperature variations at an inland station, at a considerable altitude, and

¹ This table is based on observations recorded in the *Mitteilungen aus den Deutschen Schutzgebieten*; the two following on those published by the British Association Committee.

farther removed from the equator. The high rainfall is due to the influence of the mountains; but though no month is really dry, the bulk of the rain falls between December and April. Observations for 1897 at Kibwezi, an inland station in the drier

parts of British East Africa (2° 25' S.), at an elevation of 2990 feet, show a still greater daily range of temperature, the mean for the year being 28.5°. The mean temperature for the year was 72.5°, and the rainfall (occurring chiefly in two rainy seasons, separated by a short relatively dry interval) 21.61 inches. At Machakos, a station on the higher plateau (5400 feet), the mean temperature for 1894 was 66.2 (highest month 70.2, lowest 61.4), while a four years' average of the rainfall gives 30.98 inches.

The vegetation of Africa follows very closely the distribution of heat and moisture. The northern and southern temperate zones have a flora distinct from that of the continent generally, the north corresponding with south Europe in this respect. The zones of minimum rainfall have a very scanty flora, consisting of plants specialized to resist the great dryness. The more humid regions have a richer vegetation—dense forest where the rainfall is greatest and variations of temperature least, conditions found chiefly on the tropical coasts and in the west African equatorial basin; and savanna interspersed with trees on the greater part of the plateaux, passing as the desert regions are approached into a scrub vegetation consisting of thorny acacias, &c. Forests also occur on the humid slopes of mountain ranges up to a certain elevation. The dense forests of West Africa contain, in addition to a great variety of dicotyledonous trees, two palms, the *Elaeis Guineensis* and *Raphia vinifera*, not found, generally speaking, in the savanna regions. In the latter, the most characteristic trees are the baobab (*Adansonia digitata*), Hyphæne palm, and Euphorbias. The higher mountains have a special flora showing close agreement over wide intervals of space, as well as affinities with the mountain flora of the Eastern Mediterranean, the Himalayas, and Indo-China (cf. A. Engler, *Ueber die Hochgebirgsflora des tropischen Afrika*, 1892).

The fauna again shows the effect of the characteristics of the vegetation. The open savannas are the home of large ungulates, especially antelopes, the giraffe (peculiar to Africa), and four species of rhinoceros; and of carnivores, such as the lion, leopard, hyæna, &c. The elephant (though its range has become restricted through the attacks of hunters) is found both in the savannas and forest regions, the latter being poor in large game, though the special *habitat* of the chimpanzee and gorilla. The camel—as a domestic animal—is especially characteristic of the northern deserts and steppes, while the ostrich thrives in most of the drier regions. The rivers in the tropical zone abound with hippopotami and crocodiles, the former entirely confined to Africa. The vast herds of game, formerly so characteristic of many parts of Africa, have much diminished with the increase of intercourse with the interior. Game reserves have, however, been established in South Africa, British Central Africa, British East Africa (2), Somaliland, &c., while measures for the protection of wild animals were laid down in an international convention signed in May 1900.

Of practical questions relating to the African fauna, one of the most important is that of the domestication of the African elephant. Although rarely used in modern times in any of the various ways in which the Indian species is made of service to man, it is known that the African species was tamed in ancient times. A successful experiment in this direction has lately been made in French Congo, where a young African elephant has been used at the Fernan Vaz

mission for purposes of transport, while out of eight captured in Cameroon in 1900, three have been successfully tamed. The employment of Indian elephants in East Africa was tried without much success, both by the Belgian expedition of 1879 under Captain Carter and by Count von Götzen in 1893. It is among the lowest subdivisions of the animal kingdom that the species that most injuriously affect the settlement of Africa occur. The devastation caused by locusts need not be dwelt upon, while the question of the spread of malaria by means of mosquitos has already been referred to. Hardly less detrimental by reason of the fatal effects of its bite on most domestic animals is the tsetse fly, an insect fortunately confined to Africa. Researches are being made with a view to discovering the way in which the poison acts, but though it has been proved that the blood of infected animals contains a hæmatozoon closely allied to the *Trypanosoma* present in the Surra disease of India, the endeavour to produce immunity by inoculation has so far failed, nor have any means of alleviating the disease been discovered (cf. *Proc. Roy. Soc.* vol. lxiv.).

EXPLORATION.

The last quarter of the 19th century saw the almost entire completion of the broad outlines of African geography. This period has been in the main one of filling in of detail, the wide blank space which previously occupied the centre of the continent on our maps having practically disappeared in 1877. A very brief recapitulation of the earlier stages of African exploration may be given before speaking of this later period.

After the Portuguese voyages to the East had in the 15th century made known the whole coast-line of the continent, a certain amount of progress towards a knowledge of the interior, principally in Angola and the region of the Zambezi, was made. But with the decline of Portuguese power at the end of the 16th century a period of stagnation ensued, broken only by Jesuit and Capuchin missionary enterprise in Abyssinia and Angola, and by French and English trading adventure in Senegambia. The first great advance was due to the action of the African Association (founded 1788), whose agents (Mungo Park amongst them) made known the geography of the Niger region and of various parts of Northern Africa. About 1850 began the great series of journeys, which in the south, east, and north first shed certain light on the geography of the inner regions of the continent—the discovery of the course of the Zambezi by Dr Livingstone; of the great lakes of Eastern Africa and the source of the Nile, by Burton, Speke, Grant, and Baker; and the researches of Dr Barth in the Central Sudan, being the principal results. Dr Livingstone's last great journey, commenced in 1866, began to lift the veil from the western half of the equatorial regions, but, though leading to the discovery of an entirely new river system west of Lake Tanganyika, it was brought to a close by the traveller's death (1873) before the uncertainties which attached to this new river system were cleared up. With Livingstone's death, and the universal interest aroused by the story of his labours, the latest period of African exploration may be said to have begun.

In immediate connexion with Livingstone's work was the expedition of Lieutenant Cameron, who early in 1873 left Zanzibar with the object of supporting the great explorer and carrying on independent geographical work. After learning of the death of Dr Livingstone, which occurred on 1st May¹ of that year, Cameron continued his way to Lake Tanganyika by a new route, and afterwards effected the circumnavigation of the greater part of the lake, discovering its outlet towards the Congo on the west. He then proceeded to Nyangwe, the Arab trading post on the Lualaba or Upper Congo, which had been Livingstone's farthest point on the great river; but the difficulties in the way of a further exploration of its course proving insurmountable, Cameron turned south-west through an entirely unknown region, and made his way across the southern Congo basin to Benguela on the west coast. From his view of the Lualaba, which had been at first thought by Livingstone to belong to the Nile basin, Cameron concluded that it could be nothing else than the upper course of the Congo. Meanwhile Mr H. M. Stanley, who had become famous for his relief of Dr Livingstone in 1871, started again for East Africa as correspondent of the *Daily Telegraph* and *New York Herald* to attempt the solution of the chief remaining problems of Central African geography. His first task was the thorough examination of the Victoria Nyanza, which had been held by some to consist of several independent lakes, and which he reached by a new, almost direct, route from Bagamoyo to its southern point. After circumnavigating the lake and thus proving the general accuracy of its delineation by its discoverer, Captain Speke, Stanley turned west to

survey the Albert Nyanza, reaching what he supposed to be a bay of that lake, situated under the equator, but which subsequently proved to belong to an independent piece of water. Compelled to desist from further attempts in this direction, Stanley turned south for Ujiji on Lake Tanganyika, which lake he circumnavigated, and then went west to attack the problem of the termination of the Lualaba. He, too, encountered immense difficulties in the attempt to penetrate the trackless forests of the equatorial basin, but, building a fleet of canoes, succeeded in tracing the river round its great northern bend, until after a journey of 1600 miles he finally reached the known part of the Congo, near the west coast. In this great journey he had to contend not only with natural difficulties, such as the furious cataracts by which the Congo is broken, but with the opposition of warlike cannibal tribes, through whose territory he had constantly to fight his way. The result was to bring to light a river system of hitherto unsuspected magnitude, the Congo proving to be one of the principal rivers of the globe not only in respect of volume and size of basin, but also of length of course, in which respect it is second only to the Nile among African rivers.

This great achievement helped still further to stimulate a general interest in Equatorial Africa, which had already had its outcome, since Livingstone's death, in movements destined to lead to important results. In 1873 the *West Equatorial Africa* German African Society was founded, and this body set itself the task of exploring the interior of Angola and other districts of West Africa. The success attained hardly came up to expectations, but in 1876 Dr Paul Pogge succeeded in reaching the town of the negro potentate, the Muata Yanvo. In that year King Leopold of Belgium summoned to Brussels an international conference to take measures for the systematic opening up of the continent. The outcome was the inauguration of the International African Association with its headquarters in Brussels, while committees were formed in the various European countries, the German society being reconstituted, and continuing to do good work in the southern Congo basin. On the Congo itself Mr Stanley inaugurated a great undertaking on behalf of King Leopold, which ended in the establishment of the Free State of the Congo in the basin of that river, and the exploration of its various tributary streams. Meanwhile the French had already been exploring the interior of their colony of the Gabon, the Ogowe having been explored in 1875 and 1876 by Marche and De Compiègne, and from 1875 by Pierre S. de Brazza, who, reaching the upper basin of that river, made his way across the watershed to the Congo in 1880. The whole region between the Gabon and the Congo was in time explored by French officials, among whom J. de Brazza, brother of Pierre, was one of the first to penetrate to the far north (1885). South of the Congo the Portuguese were likewise active, a great expedition being sent out in 1877 under Pinto, Capello, and Ivens, for the exploration of the interior of Angola. The first-named made his way by the head-streams of the Kubango to the Upper Zambezi, which he descended to the Victoria Falls, thence proceeding south-east to Pretoria and Durban. Capello and Ivens, after crossing the Upper Kwanza, confined their attention to the south-west Congo basin, where they disproved the existence of Lake Aquilunda, which had figured on the maps of that region since the 16th century. Farther south, in the region of the Kunene and Ovampo, good work was done in 1879 and following years by a French missionary, Père Duparquet. Following the example set by Dr Pogge, the Germans Schütt and Buchner added to the knowledge of the Muata Yanvo's empire, while Von Mechow explored the Kwango to about 5° south. The most important results were, however, obtained by Pogge and Wissmann, who passed through previously unknown regions beyond Muata Yanvo's kingdom, and reached the Upper Congo at Nyangwe, whence Wissmann made his way to the east coast. In 1884 Mr Arnot, who had reached Benguela from Natal by a route roughly the reverse of Pinto's, started west and made his way along the Zambezi-Congo watershed to Garenganze or Katanga. In 1884-85 a German expedition under Wissmann solved the most important geographical problem relating to the southern Congo basin by descending the Kasai, the largest southern tributary, which, contrary to expectation, proved to unite with the Kwango and other streams before joining the main river. Further additions to the knowledge of the Congo tributaries were made at the same time by Mr Grenfell, a Baptist missionary, who (accompanied in 1885 by Von François) made several voyages in the steamer *Peace*, especially up the great Ubangi, ultimately proved to be the lower course of the Welle. Another German expedition under Kund and Tappenbeck also made discoveries north of the Lower Kasai. In 1885-87 an Austrian expedition under Dr Lenz crossed Africa from west to east by the Congo and Lakes Tanganyika and Nyasa. Farther south Capello and Ivens in 1884-85 crossed the continent from Mossamedes to the mouth of the Zambezi, breaking new ground *en route*, especially in the borderlands between the Upper

Africa.

¹ 4th, according to the inscription cut by his followers.

Zambezi and Upper Congo. In the southern Zambezi basin and neighbouring districts, the journeys of Holub, Selous, Montagu Kerr, Erskine, and others resulted in more accurate knowledge, especially in Matabeleland and Mashonaland, while Portuguese expeditions under Paiva de Andrada explored the country south of the Lower Zambezi.

On Lake Nyasa, where a Scottish mission was established in 1875, Mr E. D. Young in 1876 for the first time reached the north end of the lake, proving that it extended farther than had been supposed. Surveys were also carried out by Mr James Stewart. In 1877 Messrs Elton and Cotterill opened a new route north of the lake to Ugogo. In

**East
Equatorial
Africa.**

East, as in West Africa, operations were started by agents of the Belgian Association, but with less success than on the Congo. The first new journey of importance on this side was made (1878-80) on behalf of the British African Exploration Committee by Mr Joseph Thomson, who after the death of his leader, Mr Keith Johnston, made his way from the coast to the north end of Nyasa, thence to Tanganyika, on both sides of which he broke new ground, sighting the north end of Lake Rukwa or Leopold on the east. In 1880-84 a German expedition under Reichard, Böhm, and Kaiser crossed Tanganyika, and penetrated beyond the Upper Congo to Katanga, while in 1882-84 the French Lieutenant Giraud proceeded by the north of Nyasa to Lake Bangweulu, of which he made the first fairly correct map. Between Nyasa and the coast useful work was done about this time by Mr H. E. O'Neill, British Consul at Mozambique, as well as by members of the Universities mission, and a little later by Mr J. T. Last. North of the Zanzibar-Tanganyika route a large area of new ground was opened in 1883-84 by Mr Joseph Thomson, who traversed the whole length of the Masai country to Lake Baringo and the Victoria Nyanza, shedding the first clear light on the great East African rift-valley and neighbouring highlands, including Mounts Kenya and Elgon. On the first part of his route he had been preceded by the German Dr G. A. Fischer, who in a second journey broke some new ground to the south and west of the Masai country, traversing for the first time the coast districts east of the Victoria Nyanza (1885-86). A great advance towards the north was made in 1887-89 by the Austrians Teleki and Von Höhnel, who discovered the large Basso Norok, now known as Lake Rudolf, till then only vaguely indicated on the maps as Samburu.

Still farther north various attempts were made between 1870 and 1886 to explore the interior of Somaliland, the principal being those of Hagenmacher (1874) and Révoil (1870-84),

**North-
East
Africa.**

but they met with only partial success. In 1885, however, the brothers James succeeded in making their way for the first time from Berbera to the Webi Shebeli. In Abyssinia and the Galla countries to the south of it the principal work was done by a band of Italian explorers, among whom the names of Antinori, Antonelli, Bianchi, Cecchi, and Chiarini most deserve mention. Many of the expeditions were unfortunate, but valuable results were obtained by Cecchi and Chiarini, who penetrated the Galla countries to Kaffa (1876-81). In 1881-83 Dr Stecker, and in 1886-87 Dr Traversi, explored the Lake Zuai region; while in 1882 a Dutch traveller, J. M. Schuver, pushed through unknown districts south-west of Abyssinia beyond the Blue Nile. French travellers, among them M. Aubry (1883-85), also made their way to the Galla countries, where a few years later a considerable advance was made by J. Borelli, who reached a point on the Omo farther south than any of his predecessors. On the Upper Nile, where General Gordon and his lieutenants were now waging war against official corruption, and the oppression of the slave traders, the chief geographical work was the survey of the course of the river by Gordon and members of his staff; the examination of the Albert Nyanza by Romolo Gessi and by Colonel Mason; and, somewhat later, various journeys of Emin Pasha to the west of the lake. To the south of Darfur the bounds of knowledge were somewhat extended by Colonel Purdy and by the Greek Dr Potagos, while on and beyond the watershed to the south-west the work of Schweinfurth was continued by the Russian Dr Junker (1878-86), who pushed far down the Welle river, and by Frank Lupton, governor of the Bahr-el-Ghazal province.

In Northern Africa, embracing the Sahara and western Sudan, the period 1873-85 was not marked by many important expedi-

**North and
North-
West
Africa.**

tions, the attention of explorers being directed to the more central regions. That of Dr G. Nachtigal, which threw valuable light on the region around Lake Chad, had been begun in 1869, though not completed till 1874. Its later stages took the traveller through the almost unknown country of Wadai to the Nile. In 1873-74 the German traveller, Dr G. Rohlfs, undertook his second expedition to the oasis north of the Libyan desert, and in 1878-79 penetrated the latter as far as Kufra. A little later (1880-81) a crossing of North Africa from east to west was effected by the Italians Matteucci and Massari, who, starting from Suakin, passed through

Wadai, and finally reached the mouth of the Niger. In the Sahara unsuccessful attempts were made to penetrate from Algeria to Timbuktu in 1873-74 by Paul Soleillet, who only reached Insalah, and in 1874-76 by Victor Largeau. In 1876-77 a German traveller, Erwin von Bary, made his way to Rhat and Air, but was assassinated. A French expedition under Colonel Flatters met with a like disastrous fate in 1881. Farther west success was attained in 1880 by a German traveller, Dr Lenz, who starting from Morocco made his way across the Western Sahara, in part by a new route, to Timbuktu. Morocco itself was, a year or two later (1883-84), the scene of important explorations by M. de Foucauld, a French traveller, who, disguised as a Jew, crossed and re-crossed the Atlas, and supplied the first trustworthy information as to the orography of many parts of the chain. In Senegambia, where the political expansion inaugurated by General Faidherbe was continued under Desbordes and Gallieni, additions were gradually made to geographical knowledge. An unsuccessful attempt to reach Timbuktu and Algeria from this side was made in 1878-79 by Soleillet, and it was not till 1887 that the former was reached by Lieutenant Caron, who navigated the Upper Niger in a gunboat. The source of the river had been reached in 1879 by MM. Zweifel and Moustier, agents of a commercial house at Sierra Leone. Behind the Gold Coast, where Kumasi, the capital of Ashanti, had long been the limit of European knowledge, the first step forward was made by Bonnat, who ascending the Volta reached the important mart of Salaga (1875-76). In 1882 Captain Lonsdale went farther, visiting Yendi and Bontuku, while two years later Captain Kirby made his way to Kintampo. On the Middle and Lower Niger no great advance was made during this period; but on its eastern branch, the Benue, good work was done by E. R. Flegel, who charted the river in 1879 during a voyage in the missionary steamer *Henry Venn*, and in 1882-83 penetrated almost to its source during an overland journey in Eastern Adamawa.

Apart from the French operations in the Sahara, Senegambia, and the Ogowe region, most of the journeys had hitherto been independent of political motives, few territorial claims having yet been made by European nations. From about 1886 onwards exploration was largely connected with the extension of political influence over African territory, inaugurated in 1884 by the annexations of Germany, and regulated by the enactments of the Berlin Conference of 1884-85, and by subsequent international agreements. The future course of exploration can best be followed by taking in turn the work done in the different spheres by European Powers. One great expedition, however, not exclusively connected with any one sphere, must be first spoken of, viz., the Emin Pasha relief expedition under H. M. Stanley, which set out in 1887 by way of the Congo to carry supplies to the governor of the old Egyptian Equatorial province. The route lay up the Aruwimi, the principal tributary of the Congo from the north-east, by which the expedition made its way, encountering immense difficulties, through the great Equatorial forest, the character and extent of which were thus for the first time brought to light. The return was made to the east coast, and resulted in the discovery of the great snowy range of Ruwenzori or Runsoro, and the confirmation of the existence of a third Nile lake discharging its waters into the Albert Nyanza by the Semliki river. A further discovery was that of a large bay, hitherto unsuspected, forming the south-west corner of the Victoria Nyanza.

In the partition of the continent among European nations, attention was first directed to West Africa, where the activity of the International Association and of France was quickly followed (1884) by the appropriation by

Cameroon.

Germany of the chief of the previously unclaimed strips of coast. In one of these—Cameroon—the unknown interior had till then been contiguous with the coast-line, but German travellers soon began to throw back its limits. Through the labours of Zintgraff (1887-89), Kund (1887-88), Morgen (1889-90), the river systems of the Sanaga and Nyong were brought to light, and a connexion effected with the Benue and Adamawa in the north. Other travellers—Von Stetten, Konrau, Ramsay, &c.—supplemented their work, while Von Uechtritz and Passarge explored scientifically the region of the Benue (1894). The eastern borders of the territory were first explored in 1897-98 by

**French
Congo.**

Von Carnap, and later (1898-99), from the side of the Congo, by Pleyn. In the adjoining French territory, the Sanga, one of the principal northern tributaries of the Congo, was explored in 1890-92 by Cholet, Ponel, Fourneau, and others, and was reached from the north by Mizon, who drew the first line of communication between the Benue and the Congo (1890-92). In 1890 Paul Crampel, who in the previous year had explored north of the Ogowe, undertook a great expedition from the Ubangi to the Shari, but was attacked and killed, with several of his companions, on the borders of Bagirmi. M. Dybowski, who commanded a supporting expedition, reached the

**Emin
Pasha
Relief
Expedition.**

Gribingi, a principal branch of the Shari. He was followed in 1892-93 by Maistre, who, reaching the Gribingi by a more westerly route, passed westward to the Benue. In 1894 Clozel reached the Wom, a south-western feeder of the Shari, which last was reached in 1896 by Gentil, who for the first time launched a steamer on its waters, and pushed on to Lake Chad, the ultimate objective of the French for many years. Further exploration in the Shari basin was effected in 1898-99 by Béhagle. Farther east, towards the Nile watershed explored first by Junker and others from the north, the pioneers from the south were Belgian officers, who went north from the Congo before the French territorial claims were fully acknowledged. Thus Hanolet reached Dar Runga, south of Wadai, while Nilis and De la Kéthulle made their way (1894) to the borders of Darfur. Subsequently French agents also pushed towards the Nile basin. In 1896-97 Liotard and Cureau reached the western borders of the Bahr-el-Ghazal, while Marchand led a large military expedition through the heart of the province, reaching Fashoda on the Nile early in 1898, and completing the crossing of the continent through Abyssinia to the east coast. Finally, in the west of the French territory, a journey from the Sanga to the coast was accomplished by Fourneau in 1898-99.

Recent exploration in the Congo State has been carried out almost entirely by Belgian officers. After the identity of the Welle with the Ubangi had been finally ascertained, and its course surveyed (1887-88) by Vangele, the upper basin of the river was traversed in all directions by Van Kerckhoven and his subordinates (1891-93), and later by Chaltin and others. Various southern tributaries of the Congo were navigated by Delcommune in 1888-89, particularly the Lukenye and the Boloko or Lomame. In 1890-92 important expeditions traversed the south-east Congo basin by overland routes to Garenganze, under Le Marinel, Delcommune, and Bia, the second of whom reached Tanganyika, and explored the course of the Lukuga. In 1896-97 the two main upper branches of the Congo and the country between them were surveyed by Lieutenants Brasseur and Cerckel, and in 1898 the southern borders of the great Equatorial forest on the eastern verge of the Congo basin were traversed by Lieutenant Glorie.

In German South-West Africa journeys were made, after the annexation of the territory, by Schenck, Schinz, Fleck, Pfeil, François, Dove, and others, who added to the knowledge of the western Kalahari as well as of the districts nearer the coast. In British South Africa Selous and Holub continued their explorations, while in 1895-96 the whole country between the Upper Zambezi and the Kafukwe was explored by Captain (now Major) Gibbons, Mr Reid, and Captain Bertrand. More recently (1898-1900), Major Gibbons, assisted by Captains Quicke, Hamilton, and others, explored the gorges of the Middle Zambezi, as well as the whole upper basin of the river. The region of Lake Ngami and the Okavango was explored and its geology elucidated in 1896-97 by Dr Passarge. On the east the boundary with Portuguese territory was surveyed in 1892 by a mixed commission, on which the British representative was Major Leverson. West of Lake Nyasa explorations were made in 1899 and 1890 by Alfred Sharpe, who in the latter year crossed the Loangwa and ascended the Mchinga escarpment; in 1890-91 by Joseph Thomson, who crossed the plateau beyond that escarpment to the neighbourhood of Lake Bangweulu, making a wide circuit to the west and south on the return journey; and more recently by Foa, Weise, Moloney, Codrington, and others, Lake Rukwa, in German territory, north of Nyasa, was visited from the south in 1889 by H. H. Johnston and Kerr Cross; in 1894 by W. H. Nutt, who made his way from the west across the Fipa plateau; and in 1897 by L. A. Wallace, who made the first complete circuit of the lake. The fact of a diminution of its area had already been ascertained by German travellers from the north. Farther west Lake Mweru, Garenganze, and the Luapula were explored in 1890 and 1892 by Alfred Sharpe, while Lake Bangweulu and the Luapula were carefully surveyed in 1895-96 and 1898-99 by Poulett Weatherley. A journey made in 1898 by Mr Campbell, a missionary, from Garenganze to Blantyre by the south of Bangweulu, also deserves mention.

In the southern districts of German East Africa, the upper basin of the Rufiji was explored in 1886 by Count Pfeil, and the country between that river and the Rovuma in 1893-94 by Von Schele and Ramsay. The hilly districts north of Nyasa have been examined by various travellers, including W. Bornhardt, who in 1896 discovered there considerable deposits of coal. Farther north the parts between the coast and Tanganyika have been surveyed by Prince, Ramsay, and others. Towards the north of the German sphere three important journeys were made across the whole width of the territory within a few years of its final acquisition. In 1891 Emin Pasha, accompanied by Dr Stuhlmann, made his way south of the Victoria Nyanza to the western Nile lakes, visiting for the first time the southern and western shores of Lake Albert Edward. In the same year Dr O. Baumann, who had already done good work in Usambara, near the coast, started on a more extended journey through the region of

steppes between Kilimanjaro and the Victoria lake, afterwards visiting the latter and exploring the head-streams of the Kagera, its chief feeder. In the steppe region above alluded to he discovered two new lakes, Manyara and Biassi, occupying parts of the East African valley system. This region was again traversed in 1893-94 by Count von Götzen, who passed to the south of Manyara, ascending Mount Gurui in its neighbourhood, and thence continuing his route westwards to Lake Kivu, north of Tanganyika, which, though heard of by Speke over thirty years before, had never yet been visited. He also reached for the first time the line of volcanic peaks north of Kivu, one of which he ascended, afterwards crossing the great Equatorial forest by a new route to the Congo and the west coast. The region of the upper Kagera and Lake Kivu has since been further explored, especially by the Germans Von Trotha, Ramsay, Bethe, Kandt, and Von Beringe, and the Englishmen Grogan and Moore, the first accurate survey of the lake being made by Kandt (1898-99). East of the Victoria Nyanza good work has been done by the zoologist Neumann, and by Von Trotha, Werther, Kaiser, and others. The exploration of Mount Kilimanjaro has been the special work of Dr Hans Meyer.

In British East Africa the Tana river districts, as far as the slopes of Mount Kenya, were explored in 1889-91 by Pigott, Dundas, Hobley, &c., and the Juba in 1891 by Dundas. The railway survey in 1892 under Macdonald gave an improved basis for the mapping of the country on the line of route, while Captain Lugard traversed the whole territory to Lakes Albert Edward and Albert in 1891-92. Valuable scientific work was done in 1893 by Dr Gregory, who ascended Mount Kenya to a height of 16,000 feet, while the country east and north of the mountain was explored between 1892 and 1896 by Chanler and Von Höhnel, A. H. Neumann, and Kolb, the last-named reaching a point only a few hundred feet below the summit. In 1893-94 Mr Scott Elliot reached Ruwenzori by way of Uganda, returning by Tanganyika and Nyasa, and in 1896 Mr Hobley made the circuit of the great mountain Elgon, north-east of the Victoria Nyanza. During the pacification of Uganda various surveys were executed by British officers. Lake Choga on the Nile between the Victoria and Albert lakes was explored in 1898 by Captain Kirkpatrick, a member of Colonel Macdonald's expedition, while the leader himself advanced north-west from Mount Elgon to the Latuka country, and Captain Austin went north to Lake Rudolf and the Omo. In 1899 Mount Kenya was ascended to its summit by a party including Mr H. J. Mackinder. Lastly, in the region of the Lower Juba, explorations were made in 1895-96 by Mr C. H. Craufurd, and in 1899 by Mr A. C. W. Jenner and Dr W. Radford.

In the Peninsula of Somaliland, &c., a period of rapid advance, due chiefly to Italian activity, began about 1890, when Bricchetti-Robecchi made a journey along the eastern coast from Obbia beyond Cape Guardafui. In the following year he went from Mukdishu to Obbia, and thence crossed through Ogaden to Berbera on the Gulf of Aden. In the same year Prince Ruspoli made his first journey-southwards from Berbera, while Baudi and Candeo penetrated to Ime on the Upper Webi, which place was also reached in 1893 by Captain Swayne. In 1892 Bottego and Grixoni left Berbera and made their way past Ime to the Upper Juba, which Bottego explored to its source, both travellers finally making their way *via* Logh to the east coast. Prince Ruspoli in 1893 reached Logh from the north, and, proceeding north-west in search of the Omo, discovered the Sagan and Lake Abbaya, but was afterwards killed by an elephant. The next expedition was that of Dr Donaldson Smith, who, starting from Berbera in 1894, explored the head-streams of the Webi, and made his way to the region of Lakes Abbaya, Stefanie, and Rudolf, ascending the main feeder of the last-named among the mountains to the north. He eventually reached the east coast at Lamu by the east of Lake Rudolf. In 1895 Bottego, accompanied by Sacchi, Vannutelli, and Citerni, left Brava with the purpose of finally solving the problem of the Omo, which some had considered unconnected with Lake Rudolf. Beyond Lake Abbaya he came upon a larger lake to the north, (Pagade or Margherita) and pushed west through mountainous country to the Omo, which he succeeded in tracing to Lake Rudolf. After exploring the west shore of that lake the explorers went north-west and discovered the head-streams of the Sobat, afterwards ascending to the Abyssinian highlands, where the leader lost his life during an attack by the natives. An English expedition under H. S. Cavendish (1896-97) followed somewhat in Bottego's steps, but after reaching the south end of Lake Rudolf went south, discovering a new lake in a volcanic region between Rudolf and Baringo. In 1897 the French traveller, De Bonchamps, traversed the southern borderlands of Abyssinia and further explored the head-streams of the Sobat, and about the same time his compatriot, M. Darragon, went south near the chain of lakes ending in Abbaya. Captain Wellby, previously known as a Tibetan explorer, took a somewhat similar route south in 1898-99,

but pushed on to Lake Rudolf, and crossed a previously unexplored tract between the lake and the Lower Sobat. In 1899 Blundell, Lovat, &c., traversed the districts south of the Blue Nile, while Donaldson Smith crossed from Berbera to the Nile by Lake Rudolf in 1899-1900.

In North Africa the last decade of the 19th century was not marked by great activity. The Sahara was crossed in 1892 from Lake Chad to Tripoli during the latter part of Monteil's journey (to be spoken of later); but in spite of the persevering efforts of the French to open a route from Algeria to the Sudan success was not attained until 1899, when M. Foureau, who year after year had returned to the task, succeeded in reaching Zinder, afterwards joining Gentil south of Lake Chad and returning by the Congo. In the Algerian Sahara surveys have been executed, partly in connexion with political movements, by Flamand, Germain, Laperrine, &c. In Southern Morocco the Tafilet oasis was reached in 1893 by a new route across the Atlas by W. B. Harris. In the western Sahara, the attempts of the Spaniards and French to penetrate inland met with little success until Adrar was reached (1900) by Blanchet.

In the western Sudan the same period was one of great activity from the Senegal to the Lower Niger and Lake Chad. In 1887-89 Captain Binger made a great journey through the Mandingo countries to Kong, and thence, after a tour to the north-east as far as Wagadugu, to the coast of Guinea. In 1890-92 Monteil made his way east across the bend of the Niger to Say, and thence to Lake Chad and Tripoli. After the French occupation of Timbuktu surveys in that region were executed by Lieutenants Hourst, Bluzet, &c., and a system of lakes communicating with the Niger was disclosed. After

SKETCH MAP OF WEST AFRICA.

the conquest of Dahomey, Say was reached from that side in 1895 by Decœur and Toutée, both of whom added to our knowledge of the Middle Niger, but more important results were obtained by Hourst, who, leaving Timbuktu in January 1896, descended the river to the sea in spite of the dangerous rapids. The southern parts of the French Sudan have since been traversed by Baud, Alby, Bretonnet, and others, and the interior of the Ivory Coast and parts of Liberia by Marchand, Hostains, Blondiaux, &c. East of the Middle Niger the expeditions of Cazemajou, and of Voulet and Chanoine, have had disastrous results.

In the British colonies, in addition to the work of various boundary commissions, the Gold Coast *Hinterland* has been penetrated as far as Gambaga and Mosi. The Germans have shown great activity in the adjoining Togoland territory, the interior being explored (1887-93) by Wolf, Von François, Kling, Büttner, and others, while in 1894-95, Drs Gruner and Doering pushed north (simultaneously with the French expedition of Decœur) through Gurma to Say, returning through Borgu, visited shortly before by Captain Lügard on behalf of the British Niger Company. East of the Niger the Benue and districts on each side have been surveyed by Macdonald (1890), and more recently by Clive, Moseley, Hewby, &c.

Trans-continental journeys not yet spoken of include those of Versepuy and De Romans, 1895-96 (Uganda, Lake Albert Edward, Equatorial forest, Congo); A. B. Lloyd, a missionary, 1898 (by a somewhat similar route); Foa, 1897 (Nyasaland, Tanganyika, Congo); and Grogan, 1899-1900 (Zambezi, central line of lakes, Nile). By the last-named the whole length of the continent from end to end was for the first time traversed.

The area of land accurately mapped in Africa is probably less than in any other continent. Although few extensive districts remain of which the general features are not now known, the cartography of by far the greater part of the continent is based merely on route surveys, carried out during more or less rapid journeys, which leave out of consideration the intervening stretches of country. Such route surveys are to a

Mapping of Africa.

certain extent supplemented by astronomical observations, which may give fairly correct latitudes, but which are rarely to be trusted as determining longitudes with close accuracy.

The countries in which exact topographical work by means of triangulation has been executed are very few, being limited to Algeria and Tunis; parts of Egypt and the Italian sphere on the Red Sea; the greater part of Cape Colony, and some portions of Natal and British South Africa. Even the results of these surveys have not yet been published in full as maps. In Egypt a survey department has lately been formed, and triangulation is proceeding at a satisfactory rate. The geodetic survey of Cape Colony is now being extended over British South Africa, work having been begun in 1897. It is hoped to carry the triangulation northwards along the 30th meridian to Lake Tanganyika, and thence with German co-operation to the Nile, and eventually down that river to Egypt. In Equatorial Africa the most accurate and most valuable triangulation yet carried out is that of Captain G. E. Smith, R.E., who, while engaged in road-making in British East Africa, executed a survey between the coast and the Victoria Nyanza, extending from Mounts Kilimanjaro and Meru in the south to Kenya and Elgon in the north. In addition to these triangulated areas fairly accurate surveys have been executed along certain lines, such as international boundaries and the tracks of railways. Among the former are the Anglo-German boundaries in East Africa from the coast to Kilimanjaro and on the Nyasa-Tanganyika plateau; the region of the Anglo-Portuguese boundary in South-East Africa; and the Anglo-French boundary behind Sierra Leone; while the most extensive railway survey, apart from the older colonies, is that from the east coast to the Victoria Nyanza.

Triangulation.

The mapping of other parts of the continent on the basis of route surveys and astronomical observations is of very varying quality. Of large-scale maps of separate European possessions the best have been supplied by the Germans, who have undertaken a complete map of German East Africa on the scale of 1:500,000. The southern part of Togoland has been mapped by P. Sprigade on the scale of 1:500,000, and the northern, with adjoining areas, on that of 1:1,000,000. Maps of all the German possessions on the scale of 1:1,000,000 are given in Langhans' Colonial Atlas, and the whole area of the Congo State has been shown on the same scale by M. Wauters in the *Mouvement Géographique*. The best maps dealing with the whole continent are those of the French "Service géographique de l'armée," on the scale of 1:1,000,000; and of Habenicht, issued by the German firm of Perthes, on that of 1:1,000,000. A movement for the better mapping of Africa was set on foot in 1895 by General E. F. Chapman, who brought the subject before the International Geographical Congress, which met that year in London. It was suggested that good results would follow from the mapping by travellers of *areas* rather than routes, and from the accurate determination of certain points in the unsurveyed portions to form a framework for the whole. For the latter object the numerous lines of telegraph now being laid down will afford great facilities, and something has already been done towards obtaining accurate longitudes by such means. The following were determined in this way in 1898-99:—

Maps based on route surveys.

TRADE AND COMMUNICATIONS.

Apart from the north and south temperate regions the commercial intercourse of Africa with the rest of the world has, for the size of the continent, remained until the present day of quite insignificant proportions. In addition to slaves, which have been furnished by the continent from the earliest times, a certain amount of gold and ivory has long been exported from the tropical regions, but no other product has supplied the material for a flourishing trade with those

Past isolation.

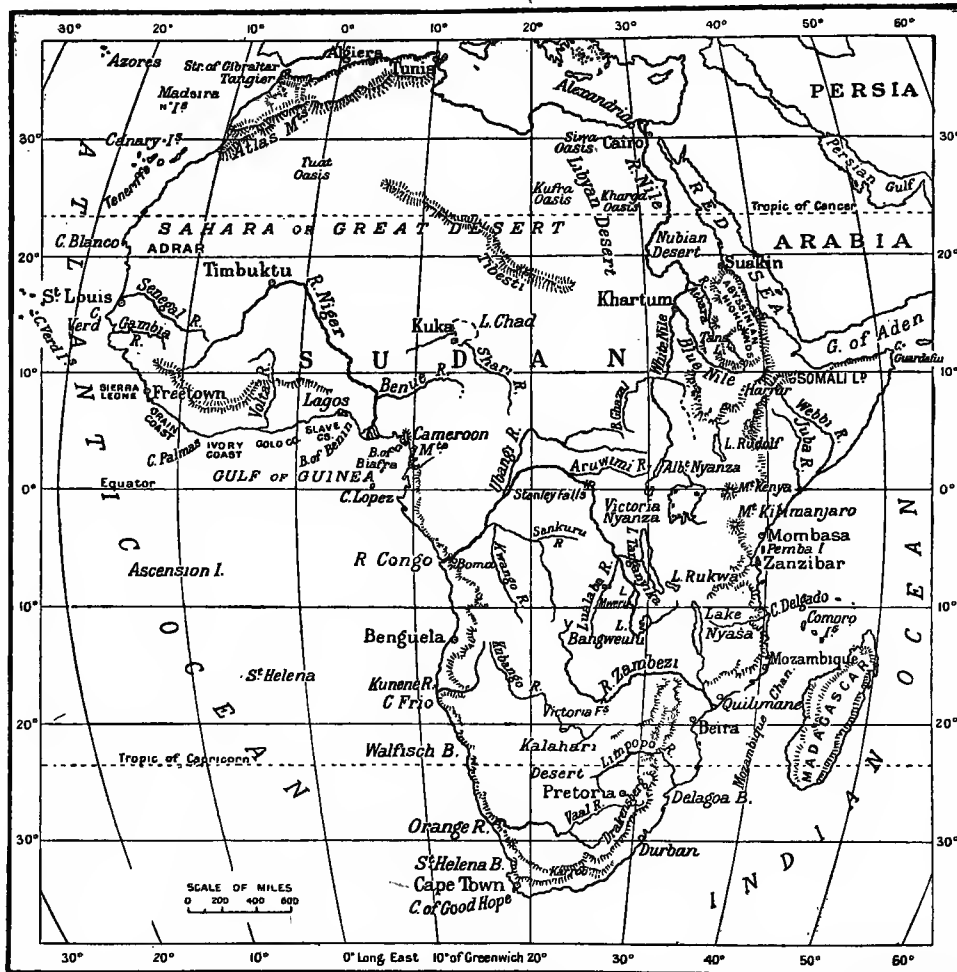

¹ The first accurate large-scale map of East Africa as a whole was compiled by Mr Ravenstein for the R.G.S. (1882).

parts. This was due not so much to the poverty of the country in natural resources, as to special circumstances which likewise caused so large a part of the continent to remain a *terra incognita* down to the 19th century. The principal drawbacks may be summarized as:— (1) Absence of means of communication with the interior; (2) the unhealthiness of the coast lands; (3) the small productive activity of the natives; (4) the effects of the slave trade in discouraging legitimate commerce. Of these the first and last are not necessarily permanent, while the third can be remedied by the introduction of Europeans as supervisors, and possibly of other races as labourers.

The resources of Africa may be considered under the head of—(1) jungle products; (2) cultivated products; (3) animal products; (4) minerals. Of the first-named the most important are india-rubber and palm-oil, which in tropical Africa supply by far the largest items in the export list. The rubber-producing plants are found throughout the whole tropical belt, and the most important are creepers of the order *Apocynaceae*, especially various species of *Landolphia* (with which genus *Vahea* is now united). In East Africa *Landolphia kirkii* (Dyer) supplies by far the largest amount, though at least four other species are known. Forms of apparently wider distribution are

Resources.

Jungle products.

SKETCH MAP OF AFRICA.

London: Stanford's Geog. Estab.

L. heudelotii, which is found in the Bahr-el-Ghazal, and extends right across the continent to Senegambia; and *L. (formerly Vahea) comorensis*, which, including its variety *L. florida*, has the widest distribution of all the species, occurring in Upper and Lower Guinea, the whole of Central Africa, the east coast, the Comoro Islands and Madagascar. In Lagos and Cameroon much rubber is produced by a large apocynaceous tree, *Kickxia africana*, and in West Africa generally by various species of *Ficus*, some promising species of which are also found in East Africa. The rubber produced is somewhat inferior to that of South America, but this is largely due to careless methods of preparation. The great destruction of vines brought about by native methods of collection has already much reduced the supply in some districts, and renders it

precarious everywhere, unless some means are taken to cultivate the rubber-yielding plants. This has already been attempted in Cameroon and elsewhere. Experiments have been made in the introduction of South American rubber plants, but opinions differ as to the prospects of success, as the plants in question seem to demand very definite conditions of soil and climate. For cultivation the *Ficus indica* is said to be a favourable tree, but possibly some endemic species of *Ficus* might prove equally valuable. The second product, palm-oil, is at present derived from a much more limited area, for although the oil palm is found throughout the greater part of West Africa, from 10° N. to 10° S., the great bulk of the export comes from the coast districts at the head of the Gulf of Guinea. A larger supply would certainly be

available, but with the risk of over-production and lower prices it is doubtful whether an increased export would be profitable. A third valuable product, but one which has not yet been made use of as it might be, is the timber supplied by the forest regions, principally in West Africa. It includes African teak or oak (*Oldfieldia africana*), excellent for shipbuilding; the durable odum of the Gold Coast (*Chlorophora excelsa*); African mahogany (*Khaya senegalensis*); ebony (*Diospyros ebenum*); camwood (*Baphia nitida*); and many other ornamental and dye woods. Some development of the timber industry has lately taken place on the Gold Coast, whence timber was exported in 1898 to the value of £110,000. Valuable timber grows too in South Africa, including the yellow wood (*Podocarpus*), stinkwood (*Ocotea*), sneezewood or Cape ebony (*Euclea*), and ironwood. Other vegetable products of importance are:—Gum arabic, obtained from various species of acacia (especially *A. senegal*), the chief supplies of which are obtained from Senegambia and the steppe regions of North Africa; gum copal, a valuable resin produced by trees of the leguminous order, the best, known as Zanzibar or Mozambique copal, coming from the East African *Trachylobium hornemannianum*, and also found in a fossil state under the soil; kola nuts, produced chiefly in the coast lands of Upper Guinea by a tree of the order *Sterculiaceæ* (*Kola acuminata*); archil or orchilla, a dye-yielding lichen (*Rocella tinctoria* and *triciiformis*) growing on trees and rocks in East Africa, the Congo basin, &c.; cork, the bark of the cork oak, which flourishes in Algeria; and alfa, a grass used in paper manufacture (*Machrochloa tenacissima*), growing in great abundance on the dry steppes of Algeria, Tripoli, &c. A product to which attention has been paid of late in Angola is the Almeida gum or resin, derived from the juice of *Euphorbia tirucalli*.

The cultivated products include those of the tropical and warm temperate zones. Of the former, coffee is perhaps the most valuable indigenous plant. It grows wild in many parts, the home of one species being in the Galla countries south of Abyssinia, and of another in Liberia. Cultivation is, however, necessary to ensure the best results, and attention has of late years been given to this in various European colonies. From Angola the export in 1897 reached a value of £175,000, but of this a large proportion was the produce of wild trees. Still more is this the case with the exports from Harrar and Abyssinia, the amount of which passing through the ports of British Somaliland reached a total of £119,000 worth in 1898-99. Encouraging results have been obtained in Nyasaland, which in 1898 exported coffee to the value of over £23,000, although the plantations are still in their infancy. Plantations have also been started in German East Africa, Cameroon, the Congo Free State, &c.

Copra, the produce of the cocoa-nut palm, is supplied chiefly by Zanzibar and neighbouring parts of the east coast. Ground-nuts, produced by the leguminous plant *Arachis hypogæa*, are grown chiefly in West Africa, and the largest export is from Senegal and the Gambia; while Bambarra ground-nuts (*Voandzeia subterranea*) are very generally cultivated from Guinea to Natal. Cloves are extensively grown on Zanzibar and Pemba islands, of which they are the staple products. The chief drawbacks to the industry are the fluctuations of the yield of the trees, and the risk of over-production in good seasons. Cotton, which grows wild in many parts of tropical Africa, is exported in small quantities in the raw state from Angola and elsewhere; but the main export is from Egypt, which comes third among the world's sources of supply of the article. Sugar, which is the staple crop of Mauritius, and in a lesser degree of Réunion, is also produced in

Natal, Egypt, and, to a certain extent, in Mozambique. Dates are grown in Tunis and the Saharan oases, especially Taflet; maize in Egypt, South Africa, and parts of the tropical zone; wheat in Egypt, Algeria, and the higher regions of Abyssinia; rice in Madagascar. Wine is largely exported from Algeria, and in a much smaller quantity from Cape Colony; fruit and vegetables from Algeria. Tobacco is widely grown, on a small scale, but, except perhaps from Algeria, has not yet become an important article of export, though experimental plantations have been tried in various tropical colonies. Cacao and tea have also been tried in some of these, but their cultivation has hardly advanced beyond the experimental stage. The most promising cacao plantations are along the coast of Cameroon, whence the product was exported in 1898 to the value of £15,000. Indigo, though not originally an African product, has become naturalized and grows wild in many parts, while it is also cultivated on a small scale, but is not likely to become an important article of export. The main difficulty in the way of tropical cultivation is the labour question; but some races, such as the Angoni of Nyasaland, have proved good workers, while the introduction of Indian coolies is regarded in some quarters as the solution of the difficulty.

For the study of economic botany, and the development of tropical cultivation, botanical gardens have been established in many of the European possessions, including the Gold Coast, Lagos, Sierra Leone, Old Calabar, Cameroon, British Central Africa, Uganda, and German East Africa.

Of animal products one of the most important at present is ivory, the largest export of which is from the Congo Free State. The diminution in the number of elephants with the opening up of the remoter districts must in time cause a falling-off in this export. Beeswax is obtained from various parts of the interior of West Africa, and from Madagascar. Raw hides are exported in large quantities from South Africa, as are also the wool and hair of the merino sheep and Angora goat. Both hides and wool are also exported from Algeria and Morocco, and hides from Somaliland. Ostrich feathers are produced chiefly by the ostrich farms of Cape Colony, but some are also obtained from the steppes to the north of the Central Sudan. Live stock, principally sheep, is exported from Algeria and cattle from Morocco.

The hitherto exploited minerals of Africa are confined to a few districts only, the resources of the continent in this respect being largely undeveloped. Since the discovery of gold in the Transvaal, particularly in the district known as the Rand (1885), the output has grown enormously, until in 1898 it reached a value of over 15 millions sterling. The gold-yielding formations extend northwards through Mashonaland, which may produce a large amount in the future, and deposits may possibly be discovered in various parts of tropical Africa where ancient schistose rocks occur. In the Galla countries gold has long been an article of native commerce, and on the Gold Coast of European also. Copper is found in the west of Cape Colony, in German South-West Africa, and in the Garenganze or Katanga country in the southern Congo basin, where it has long been exploited by the natives. It also occurs in Morocco, Algeria, Darfur, &c. Iron occurs in Morocco and Algeria (some being exported from the latter), and is widely diffused, and worked by the natives, in the tropical zone. But the deposits are generally not rich, and European iron already competes with the native supply. Coal is worked, principally for home consumption, in Cape Colony, Natal, and Orange River Colony, and has lately been dis-

Animal products.

Minerals.

Cultivated products.

covered in workable deposits in the German territory north of Lake Nyasa. Diamonds are found in large quantities in a series of beds known as the Kimberley shales, the principal mines being at Kimberley, in the north of Cape Colony. Phosphates are exported to some extent from Algeria. Of other minerals which occur, but are little worked, zinc, lead, and antimony are found in Algeria, lead and manganese in Cape Colony, plumbago in Sierra Leone.

Of the natural resources here enumerated those from which a future increase of trade may be expected are probably the plantation products, the cultivation of which is still in an experimental stage. For such a development, however, the solution of the labour problem and the provision of adequate means of transport (to be spoken of later) are indispensable conditions. The country which under a civilized Government would perhaps give the greatest scope for development is Morocco, both the soil and climate of which are exceptionally favourable, while the mineral resources are also considerable. British South Africa, too, contains many valuable minerals besides gold, which will no doubt in time be exploited.

The imports from foreign countries into Africa consist chiefly of manufactured goods, varying in character according to the amount of settlement by Europeans. In Algeria and South Africa they include most of the necessities and luxuries of civilized life, manufactured cotton and woollen goods, especially the former, taking the first place, but various food stuffs, metal goods, coal, and miscellaneous articles being also included. In tropical Africa, and generally where few Europeans have settled, the great bulk of the imports consists as a rule of cotton goods, the only articles for which there is much native demand. This absence of a large demand for European goods is in fact a great obstacle to trade with Central Africa, but with the gradual advance in civilization it may in time be removed. Perhaps the most promising field in this respect is to be found in the populous and comparatively civilized countries of the Central Sudan, reached from the Lower Niger.

The following tables show, so far as statistics are available, the total imports and exports of the various countries for 1898, and also the chief sources of supply of the principal African commodities. Any estimate, based on these figures, either of the total commerce of Africa, or even of the external trade, can only be very vague. No figures are given for inland countries, partly for want of statistics, and partly because the transit trade to and from these already appears under the countries through which it passes. In estimating the total external trade, the special trade only of Zanzibar must be included, as the remainder appears under the countries of the opposite mainland. But in the case of Portuguese East Africa the general trade may be taken, as no figures are given for the adjoining inland countries. A certain amount of local trade between contiguous countries, as, *e.g.*, between Lagos and Dahomey, is of necessity included, but this is possibly not more than enough to balance the absence of figures for certain other countries. The totals thus obtained are:—Imports, £66,828,000; exports, £67,675,000; total, £134,503,000. In 1896 an estimate, probably based on the statistics for 1894-95, gave the grand total as roughly £100,000,000. The increase in about four years would thus be 34 per cent.

No continent has in the past been so backward in respect of means of communication as Africa, and it was only in the last decade of the 19th century that decided steps were taken to remedy these defects. The African rivers, with the exception of the Middle Congo and its affluents, are generally unfavourable to navigation, and throughout the tropical region almost the sole routes have been native footpaths, admitting the passage of a single file of porters, on whose heads all goods have been carried from place to place. Certain of these native trade routes are, however, much frequented, and lead for hundreds of miles from the coast to the interior. In the desert regions of the north transport is by caravans of camels, and in the south ox-waggons have, until quite recently, supplied the general means of locomotion. On the east side the principal termini of the native trade routes are: Suakin, for the Egyptian Sudan; Massawa, for Abyssinia; Zeila and Berbera, for the Somali and Galla countries; Mombasa and Pangani, for the Masai countries, &c.; Bagamoyo, for the Victoria Nyanza (south), Tanganyika, and Nyasa (north), and for the countries west of Tanganyika; Kilwa, Lindi, Mozambique, and Quilimane for Southern Nyasa and the countries beyond.

On the west side there are fewer important native routes, the dense forests of Guinea proving a barrier to intercourse, while the Central Sudan states have in the past communicated rather with the north across the Sahara than with the shores of the Atlantic. In Senegambia the most frequented routes have long been those up the Senegal and Gambia rivers. In Upper Guinea the chief are those leading north from the Gold Coast, Togoland, and Dahomey ports to the interior markets of Yendi, Sansanne Mangu, and Sansan Hausa on the Niger,³ and from Lagos to the Niger and Sokoto. South of the equator the principal long-established routes are those from St Paul de Loanda to the Lunda and Baluba countries; from Benguela *via* Bihe to Urua and the Upper Zambezi, and from Mossamedes across the Kunene to the Upper Zambezi. In South Africa the ox-wagon routes, now partially superseded, made for Lake Ngami, the Middle Zambezi, and Matabeleland from Walfisch Bay and the middle course of the Orange river, while others traversed the Orange River Colony and Transvaal to the Limpopo and beyond. In the north the principal caravan routes across the Sahara lead from different points in Morocco and Algeria to Timbuktu; from Tripoli to Timbuktu, Kano, and other great marts of the Central Sudan; from Bengazi to Wadai: that from Siut on the Nile through the great oasis and the Libyan desert to Darfur, &c., has been disused of late. Important routes also traverse the Sudan states from west to east, and proceed south to Adamawa from the commercial centres of the Hausa countries.

Some of these native routes are now being superseded by the improved communications introduced by Europeans in the utilization of waterways and the construction of roads and railways. Steamers have been conveyed overland in sections and launched on the interior waterways above the obstructions to navigation. On the Upper Nile and Albert Nyanza their introduction was due to Sir S. Baker and General Gordon (1871-76); on the Middle Congo and its affluents to Sir H. M. Stanley and the officials of the Congo Free State, as well as to the Baptist missionaries on the river; and on Lake Nyasa to the supporters of the Scottish mission. The comparative freedom from obstruction between the sea and this lake has led to the introduction on it and on the rivers leading to it of a flotilla of steamers (including gunboats belonging to the British Navy) by which—apart from a short interval broken by rapids on the Shiré—water communication is supplied from the sea to the north end of the lake, beyond which the Stevenson road affords easy communication with Tanganyika. Here a steamer is being built by a British company, while a small

vessel was launched on Lake Mweru in 1900. The Germans have also a steamer on Nyasa, and in 1900 another was launched on Tanganyika, where a British sailing vessel had already plied for some years. A river steamer has been placed by the Germans on the Rufiji. A small vessel was launched on the Victoria Nyanza in 1896 by a British mercantile firm, and a larger Government steamer made its first trip in November 1900. On the Niger and Benue, where navigation is open from the sea for a considerable distance into the interior, steamers have plied for many years, while the French have placed steamers on the navigable portion of the upper river. The middle course of the river is only just navigable for part of the year. A small steamer for the navigation of the Shari and Lake Chad was taken out by the Gentil expedition, by way of the Congo, in 1896-97.

Roads suitable for wheeled traffic, even of the most primitive kind, are still few. The first attempt at road-making in Central Africa on a large scale was that of Sir F. Buxton and Mr (afterwards Sir W.) Mackinnon, who completed the first section of a track leading into the interior from Dar-es-Salaam (1879). A still more important undertaking was the road, begun in 1881, from the head of Lake Nyasa to the south end of Tanganyika, constructed mainly at the expense of Mr James Stevenson, which forms a link in the "Lakes route" into the heart of the continent. In British East Africa a road was made from Mombasa to Kihwezi under the auspices of the British East Africa Company, and afterwards continued for the British Government by Captains Sclater and Smith to Port Victoria on the Victoria Nyanza. From Kikuyu it descends to the great rift-valley, on the farther side of which it ascends the Mau Escarpment near the Eldoma ravine. The continuation, 400 miles long, was begun in 1895 and completed in about two years at a cost of some £17,000. In German East Africa the caravan track to Tanganyika has recently been much improved and other roads made, generally with a width of 5 to 6 metres, while transport by means of mule carts has been initiated. In Cameroon a road has been made from Victoria northwards to Buea, and others are contemplated. In Madagascar a road 5 metres broad, macadamized to a width of 3 metres, was under construction in 1900 between Antananarivo and the coast at Andevorante, between which place and Tamatave communication is maintained both by a shore road and by the line of lagoons. Farther north the construction of a road from the capital to Mevetanana, whence water transport is available to Majunga, was begun in 1897.

Although still occupying a low place among the continents in the matter of railway communication, Africa was during the last decade of the 19th century the scene of an important development in that direction. In 1890 **Railways.** African railways were almost entirely confined to the extreme north and south (Egypt, Algeria, Cape Colony, and Natal); while apart from short lines in Senegal, Angola, and at Lourenço Marques, the rest of the continent was wholly without a railway system. In Egypt the Alexandria and Cairo railway dates from 1855, while in 1877 the lines open reached about 1100 miles, and in 1890, in addition to the lines traversing the delta, the Nile had been ascended to Assiut. In Algeria the construction of an inter-provincial railway was decreed in 1857, but was still incomplete twenty years later, when the total length of the lines open hardly exceeded 300 miles. Before 1890 an extension to Tunis had been opened, while the Atlas had been reached by the lines to Ain Sefra in the west and Biskra in the east. In Senegal the railway from Dakar to St Louis had been commenced and completed during the 'eighties, while the first section of the Senegal-Niger railway, that from Kayes to Bafulabe, was also constructed during the same decade. In Angola a line from Loanda towards the interior, bearing the ambitious title "Royal Trans-African Railway," had been opened for a short distance before 1890. In Cape Colony, where in about 1880 the railways were limited to the neighbourhood of Cape Town, Port Elizabeth, and East London, the next decade saw the completion of the trunk-line from Cape Town to Kimberley, with a junction at De Aar with that from Port Elizabeth, as well as of the lines from Port Elizabeth to Graaf Reinet, and from East London to Burghersdorp. The northern frontier had, however, nowhere been crossed. In Natal, also, the main line had not advanced beyond Ladysmith. In the neighbouring Portuguese territory the line from Lourenço Marques towards the Transvaal, commenced in 1887, had not quite reached the frontier when seized by the Portuguese authorities in 1889. Within the Transvaal the railway to Pretoria was, however, under construction.

Recent railway development was inaugurated by the scheme for the Congo railway, connecting the navigable portions of the upper and lower river, operations on which had been begun before 1890, but which was not opened throughout until July 1898. A little later the Angola railway was opened as far as Amhaca, while its extension to Malanje has been decided upon. In East Equatorial Africa a beginning

¹ In 1897.

² Exclusive of export from Mogador.

³ The former trade centres, Kong, Salaga, and Say, have lately lost their importance.

was made by the construction, within the German sphere, of a short line from Tanga towards Usambara; but in spite of many schemes for a trunk line to the great lakes, no decided action had yet been taken in 1901, the necessary credits for the expenses of a line from Dar-es-Salaam to Tanganyika, with a branch to the Victoria Nyanza, having been refused. In British East Africa a survey for a railway to the Victoria Nyanza was carried out in 1892, and the first rail laid in 1896. The route adopted, after traversing Kikuyu, drops down to the rift-valley by a steep and difficult descent, afterwards climbing the Mau Escarpment to Port Florence on Kavirondo Bay. In April 1901, 488 miles had been completed out of a total of 582. In French Somaliland a railway is under construction from Jibuti to Harrar, with the object of tapping the trade of Abyssinia. In British Central Africa a scheme has been set on foot for a railway past the rapids of the Shiré. In South Africa the Cape trunk-line has been continued *via* Mafeking to Bulawayo, which was reached in 1897, while a line from Beira to Salisbury, commenced in 1891, was completed in 1899. The Natal and Cape railways have been continued north to the Transvaal (the latter traversing the whole length of Orange River Colony), meeting the completed Lourenço Marques railway at Pretoria. Other lines have also been constructed or commenced both in the Transvaal and Orange River Colony. In 1899 a northern extension of the Bulawayo railway, towards the Zambezi, was commenced as a section of a great scheme for a railway from end to end of the continent, passing through German East Africa and Uganda to Cairo; while another step towards the realization of the project was taken in the same year by the completion of the Nile railway to Khartum. Pending a possible extension to the Upper Nile, steam communication by river in that direction was opened by the cutting of the *sudd*, or grass barrier, early in 1900 by Major Peake. Another Egyptian railway which is probably only a question of time is one from Suakin to Berber or Kassala. Farther south a short line has been open for some years at Massawa. In Algeria an extension of the western railway was opened to Jenien-bu-Resg at the beginning of 1900, while the much-discussed project of a line or lines across the Sahara to Timbuktu and Lake Chad has again come into prominence. In French West Africa the construction of a line from Konakri to the Upper Niger has been commenced, while work on the Senegal-Niger line has been continued. On the Ivory Coast the survey for a proposed railway towards the interior was completed in 1899, and in Dahomey a line from Kotonu to the Niger, by a route passing through Carnotville and Nikki, has been begun. In French Congo, although the need of a line to Brazzaville on Stanley Pool is acknowledged, little progress towards a realization of the project has been made. In the British West African colonies lines have since 1896 been under construction in Sierra Leone, the Gold Coast, and Lagos. In the Congo Free State a short railway to Mayumbe, north of the lower river, is being constructed, and lines are proposed from Stanley Falls to Albert Nyanza and Tanganyika. Finally, in Madagascar, the credits for a line from Tamatave to the capital were voted early in 1900.

The telegraphic system of Africa is on the whole older than that of the railways, the newer European possessions having in most cases been provided with telegraph lines before railway projects had been set on foot. In Algeria, Egypt, and Cape Colony the systems date back to the middle of the 19th century, before the end of which the lines had in each country reached some thousands of miles. In tropical Africa the systems of French West Africa, where the line from Dakar to St Louis was begun in 1862, are the most fully developed, lines having been carried from four different points on the coast of Senegal and French Guinea towards the Niger, the main line being prolonged north-west to Timbuktu, and west and south to the coast of Dahomey; while other lines are either open, being constructed, or projected, including one connecting the Ivory Coast with the general system. In French Congo, also, a line connects Brazzaville with the coast at Loango, whence it runs northwards to Libreville. Most of the European colonies and protectorates have lines of more or less length, but the most important is that initiated by Mr Cecil Rhodes, which, starting northwards from the Cape, is destined before long to connect the north and south extremities of the continent. It crosses the Zambezi to Lake Nyasa, beyond which it has already passed the south end of Tanganyika, while from the north the Egyptian lines have been prolonged beyond Khartum to the Upper Nile. A line from the east coast, which will eventually connect with the Cape to Cairo line in Uganda, has been carried through British East Africa in advance of the railway, reaching the Nile at Ripon Falls in February 1900. Considerable progress has been made with a line which will cross the whole width of the Congo Free State to Lake Tanganyika, where it may eventually be connected with the German line from Dar-es-Salaam to the lake.

(E. HE.)

II. ETHNOLOGY.

That Africa has been continuously occupied by two distinct branches of mankind—the *Caucasic* and the *Ethiopic*—from the remotest times, seems evident both from the remains of primitive man which have been found wherever they have been sought, and from the ethnical relations that have prevailed throughout the historic period. The remains—that is, rude and polished flints and other implements dating from the Old and New Stone Ages—have in recent years been brought to light in great abund-

ance in the extreme north and south, and in several intermediate places, under conditions which leave no doubt that the whole area was peopled since the early Pleistocene, if not even the late Pliocene, epoch. Thus, in Egypt Professor Flinders Petrie has collected large quantities of Palæoliths on the limestone Abydos plateau, 1400 feet above the present Nile level, and others embedded in the ancient gravels of the former High Nile, when the main stream still rolled down fifty times its present volume. In the same region of Upper Egypt M. J. de Morgan has identified four stations where primitive man worked his rude weapons, and where Oppert finds indications of a thoroughly established social and political organization in the New Stone Age, some 12,000 years before the new era. In Tunisia M. A. Dumont found flints in abundance under limestone beds deposited by a river which has since disappeared, and declares that the origin of man in Mauritania must be set back to an age which deranges all chronology and confounds the very fables of the mythologies. The same inference is drawn by Sir John Evans from the results of Mr Seton Karr's researches in Somaliland, while the wide range of early man is further attested by the objects recovered by Sir R. Burton in Upper Guinea, and by W. D. Cooch and J. Sanderson in Cape Colony and Natal.

All the works of the Old Stone Age present, wherever found, a striking resemblance in their appearance, form, and method of production, implying that they date from an age when all the inhabitants of Africa were still of one type and stood at the same low stage of culture. They appear to have migrated westwards from Indo-Malaysia, probable cradle of mankind, in two streams, one by the not yet submerged or but partly submerged Indo-African continent, now flooded by the Indian Ocean; the other, by the overland Asiatic route, which was also followed by the large partly extinct and partly surviving Pliocene and Pleistocene mammalian fauna.

In their new homes these two groups, originally of the same generalized proto-human Pleistocene type, gradually became specialized under the influence of the different physical environments—relatively hot and dry in the north, hot and moist in the south. Thus may well have arisen on African soil the two now highly specialized divisions of mankind which share the continent between them, although the process of specialization may have been, and probably was, already in progress before their arrival. It now becomes easy to understand how what are accepted as the highest and the lowest sections of the human family are found occupying conterminous domains since prehistoric times, the southern stream being still represented by the Negro or black populations of Sudan and thence southwards to the extremity of the continent, the northern by the Caucasian or white populations of the Sahara, and thence northwards and westwards into Europe and Asia. We also see how unnecessary it is with a former school of anthropologists to derive the whites from their black neighbours, or, a still more difficult process, the blacks from the whites. Both have been involved independently in their present respective *habitats*, where they may therefore be regarded as aborigines in the strict sense of the term.

But the two ethnical zones are nowhere separated by any marked mountain barriers except in the eastern (Abyssinian) highlands, or even by great marine or desert spaces, such as would be impassable by primitive man, for we now know that at all events since the early Tertiary epoch the Sahara has been dry, and, till later times, even habitable land, and not, as formerly supposed, a marine basin. Hence there have been constant and continuous overlappings and interminglings all along the ethnical divide, and as the large fauna—elephant, hippopotamus, giraffe, lion, hyæna, ostrich—range over the whole continent, so the dark Sudanese peoples have encroached at various points—Tibesti Range, Nile Valley, &c.—on the Caucasian domain, while the Caucasians have to a far larger extent penetrated into the Negro zone, reaching especially on the eastern seaboard to the southern limits of the mainland.

These diverse secular blends have resulted in a multitude of transitional forms between the two primeval stocks, presenting a kaleidoscopic picture which has been further complicated by the intrusion of numerous foreign elements—Semitic Himyarites, Phœnicians, and Arabs, Greeks, Romans, Vandals, Malays, Hindus, modern Europeans, and others—generally round the periphery, but in some cases penetrating far into the interior.

But amid all this ethnical confusion the two original groups have in many places preserved their racial purity almost intact,

so that a tolerably correct estimate may still be formed of their essential physical characters. The *Hamites*, as the Caucasian aborigines are conventionally called, present striking analogies both with the Asiatic Semites and with the South Europeans, so that by many ethnologists all are regarded as belonging fundamentally to one stock, collectively classed as *Afro-Europeans* or *Mediterranean*. Thus many of the Mauritanian Hamites (Berbers of Morocco, Algeria, and Tunisia) are of even lighter colour than the Spaniards or Italians, with blue eyes, yellow or brown beard, oval head of the long type, large straight or aquiline nose, perfectly regular features, shapely build, medium height, and altogether exceedingly handsome men. Similar traits occur amongst their southern kinsmen, the *Tuaregs* of the Western Sahara, and even amongst the *Fellahin*, of Egypt, who, however, are generally of swarthier complexion and often startlingly like their *Retu* ancestors, as figured and carved on the old Egyptian monuments. Still darker are the *Herratin*, or "Black Berbers," of the Southern Atlas, and all the eastern Hamites between Egypt and the equator, who betray a varying strain of negro blood in their tumid lips, and especially in their crisp or ringlety and always black hair.

The Hamitic language also, which is of the inflecting order, presents several features in common with the Semitic, on the one hand, and on the other with the old Iberian, still surviving in the Basque of the Western Pyrenees. This Hamitic form of speech, which, like the Semitic and unlike the Aryan, is of an extremely tenacious character, pervades the whole of the African Caucasian domain, where it has been current for countless ages, and had already been reduced to written form by the Egyptians some 5000 or 6000 years before the new era. Letters were also known in remote times to some other members of the Hamitic family, as shown by the not yet deciphered rock inscriptions in the Nile valley above Egypt, and in the peculiar *Tafnagh* script still in restricted use amongst the Mauritanian and Saharan Berbers.

Except in Egypt, where all were merged many millenniums ago in a single despotic monarchy, the Hamitic peoples have always shown a marked tendency towards Democratic institutions. In the tribal system everything is regulated by the public assembly, in which all have a voice, so that the Berber is what he calls himself, *Amazigh* (plural *Imazighen*, the national name), a "free-man," whereas the more theocratic and feudal Semitic community is ruled by a despotic hereditary sheikh. The Berber is also less fanatical, though all have long been Mohammedans, more generous to his womenfolk, and of rather sedentary habits, preferring fixed dwellings and agriculture wherever possible to the tent-life of the nomad Bedouin stock-breeder. Pastoral ways, however, prevail largely amongst the Eastern Hamites—Bejas, Somali, Gallas, Turkanas, Masai—who roam the steppe lands between the Nile and Red Sea and the Mau plateau, which are unfavourable for tillage. Hence it is that the Wahumas, who are of Galla descent, retain their nomad pastoral habits amid the Bantu Negroid populations of East Central Africa.

The negroes themselves, whose physical and mental characters are elsewhere described (Art. NĒGRO), form almost everywhere settled agricultural communities. But this is not due to any superiority over the nomad Hamites and Semites, to whom they are greatly inferior in most respects, but to the nature of their environment, which, lying mainly between the tropics, enjoys an abundant rainfall, and is consequently more favourable for agriculture than for pasturage. Hence it is that the inhabitants of the arid south-western steppes (Damara and Namaqua lands) form an exception to the general rule, and are excellent herdsmen, but cultivate very little land. Compared with the Hamites, the negroes are also extremely cruel and superstitious, and with the exception of the mixed negroid populations of Sudan—*Songhay*, *Hausas*, *Baghirmi*, *Kanuri*, *Mabas*, and others now mostly Mohammedans—are still mainly pagans, though Christianity has made some progress amongst the *Waganda* of Lake Victoria, and the Zulus-Xosas, Basutos, and Bechuanas of the extreme south. Ancestor-worship prevails on the eastern, nature-worship on the western seaboard, with interminglings in the interior. This is clearly seen by the distribution of the two chief names of the Deity—*Munkulunkulu*, "Great-grand-Father," and *Neambi*—of uncertain meaning, but indicative of the forces of nature, variants of which terms occur, the former almost exclusively along the east, the latter along the west side of the continent, while both are intermingled in the central regions.

It is further to be noticed that the two primordial stocks—the white and the black—are found from remote times already divided into several secondary groups, whose obscure inter-relations still offer many difficult problems to the ethnologist. In general such secondary groups are far less aberrant from the normal type, and more easily accounted for, in the Caucasian than in the negro domain. Amongst the Hamites the chief divergences are represented by the *Nubians* of the Nile valley above Egypt, who are usually regarded as Hamites with a black strain, but are on the contrary true negroes with a Hamitic strain (Art. NUBIA); the *Tibbus* of the Eastern

Sahara, treated as negroes with a Hamitic strain, but undoubtedly true Hamites, merging gradually southwards in the black populations of the Chad basin (Art. *TIBBUS*); the *Fulahs* of West and Central Sudan, often allied to the *Nubas*, with whom they have nothing in common, being originally Hamites, now fused in many places with the surrounding negro peoples; lastly, the *Fans* of the Ogway basin, the *Masai* east of Lake Victoria, the *Turkanas*, *Hendilehs*, and others of Lake Rudolf, and the *Wahumas*, widely diffused under many names throughout East Central Africa. These also are undoubtedly Hamites, mixed in varying proportions with negro elements.

But the secondary groups of the negroes themselves are not so easily explicable. Here the *SUDANESE NEGROES* have in the first place to be distinguished from the multitudinous *BANTU NEGROID* groups, who occupy most of the southern half of the continent, from about 4° or 5° N. lat. to Natal and Pondoland. Although not always easily justified on anatomical grounds, this distinction between the northern Sudanese and southern Bantu sections of the negro family has a practical value and a substantial foundation in the geographical distribution, the mental qualities, and the speech of the two groups. No full-blood Sudanese Negro community has ever developed a political or social system higher than that of the tribal organization, while extensive kingdoms and empires, such as those of the *Monomotapa*, of the *Cazembo*, of *Lunda*, *Barotseland*, *Kongo*, and *Zululand*, based on unwritten codes and military institutions, have flourished often for several generations amongst the Bantu peoples. Nor have any true Sudanese Negroes ever acquired prominence for great intellectual or moral qualities, such as those by which several of the *Tushilonges*, the *Balolo*, the *Makololo*, *Bechuana*, *Basuto*, and *Zulu-Xosa* rulers have been distinguished in former and recent times. In a word, the average Bantu is altogether more intelligent and far more capable of upward development than the average Sudanese Negro.

Very marked from this point of view are the contrasts presented by both groups in the linguistic domain. While all speak languages of the agglutinating order, linguistic chaos prevails in Sudan, linguistic uniformity to a remarkable degree in Bantuland. The numerous dialects current amongst the Bantu peoples and diffused over an area of some 6,000,000 square miles are all reducible to half-a-dozen groups, which are themselves closely related and obviously all sprang from a single stock language presenting some structural features of a high order. *Kongoese*, a typical member of the family, possesses the qualities of precision, flexibility, and subtlety of expression to such an extent that "its daily use is in itself an education" (Rev. W. H. Bentley). In Sudan, on the contrary, the countless local dialects defy classification. The *Nuba* of Kordofan and Nubia differs as profoundly from the *Fulah* of Senegambia, the *Songhay* of the Middle Niger from the *Kanuri* and *Baghirmi* of Lake Chad, as English does from Arabic, or French from Chinese. In a word these Sudanese tongues may be grouped in a large number of families which are radically distinct from each other, and, whatever their origin, can no longer be traced to a single stock.

From these remarks it follows that the term "Sudanese" has a distinctly racial, but no linguistic value, whereas the term "Bantu" is primarily linguistic. It conveys a very clear idea to the philologist, but not to the anthropologist, who finds in the mixed Bantu domain not only every shade of transition between the true negro and the true Hamite, but also some divergent types differing greatly from both. In the tropical forest tracts are scattered numerous groups of *NEGROIDS*, or "Little Negroes," true dwarfs, differing not only in their diminutive stature (3 ft. 6 in. to 5 ft.) but also in some other important respects—yellow colour, hirsute bodies, culture (all hunters exclusively)—from the blacks of normal type. Lastly, in the extreme south-west, range the primitive *BUSHMEN*, still at the Palaeolithic stage, and the neighbouring *HOTTENTOTS*, both presenting some remarkable and highly specialized features, such as the *tablier* and *steatopygia* peculiar to the female sex, and a distinctly yellow complexion common to both. (Art. *BUSHMEN*; *HOTTENTOTS*.)

Thus is completed the variegated picture presented by the aboriginal inhabitants of the continent. Of the intruders immeasurably the most important from the ethnical, but no longer from the political, standpoint are the *SEMITES*, who arrived from Asia, some in prehistoric, some in historic times, mainly by the Mediterranean and by the two routes at the southern and northern extremities of the Red Sea. Amongst the earliest arrivals were the civilized peoples of Arabia Felix (Yemen), *i.e.*, *Minaeans* and *Sabaans*, collectively known as *Himyarites*, or "Red Men" (whence the "Red Sea"), who established themselves about Adulis bay some centuries before the new era. Thence they penetrated gradually into the Abyssinian uplands, founding the Axumite empire, yielding later to the religious and cultural influences of the Alexandrian Greek and Coptic Christians, and intermingling everywhere with the rude Hamitic aborigines (*Agaus*).

Thus were formed the extremely mixed populations of Abyssinia, while the dominant Semitic immigrants continued and continue to

hold the political overlordship, founding the three kingdoms of Tigré, Amhara, and Shoa, at present united in the empire of "Ethiopia," as it is officially called. The old Hamitic speech is not extinct, although everywhere somewhat eclipsed by various more or less corrupt forms of Geez, *i.e.*, the archaic Semitic tongue, which was introduced by the Himyarites, still survives in the Marah district of South Arabia, and is the liturgical language of the Abyssinian Christians.

The Himyarites, who took the southern route, were probably preceded by their Phœnician kinsmen, who had already at an early date converted the Mediterranean into a great highway of trade and colonial enterprise. From the great cities of Tyre and Sidon came the founders of the greater cities of Leptis Major, Utica, Carthage, and other Phœnician settlements on the coast lands between the Syrtes and the Atlantic, later merged in the Carthaginian empire, which contended with Rome for the mastery of the ancient world. After the fall of Carthage the Phœnician settlements everywhere became Romanized, and both the Romans and their Vandal conquerors were all in their turn absorbed by the surrounding Hamitic aborigines.

Then came the third great Semitic invasion, that of the fiery *Arab* fanatics, which has modified the ethnical relations of the continent to a far greater extent than all the other intrusions together. Before the close of the 7th century the Moslem Arab hordes had already reached the shores of the Atlantic, and soon after spread over the western Sahara, founded Mohammedan states (Timbuktu, Bornu, Baghirmi, Wadai) on the banks of the Niger and in the Chad basin, penetrated up the Nile valley to and beyond Khartum to the Sobat junction, developing great pastoral communities and even states—Kabbabish, Jaalins, Baggaras, Fúnj empire of Senaar—in the present Anglo-Egyptian Sudan; lastly, established themselves on the eastern seaboard from Cape Guardafui to Sofala beyond the Zambezi, everywhere dominating, but also intermingling with the aboriginal Hamitic, Negro, and Negroid Bantu populations.

Still later the Arabs advanced from the coast lands and the White Nile far inland, ranging over vast spaces westwards to the Upper Congo and southwards to Lakes Tanganyika and Nyasa, in association with their *Nubian*, *Swahili*, *Ajao*, *Manyuema*, and other native allies. Here also were founded some permanent settlements—*Mpwapwa*, *Tabora*, *Ujiji*, *Nyangwe*, *Kota-Kota*, *Riba-Riba*, *Meshraer-Rek*, *Lado*—which, however, were not so much Arab colonies as *zeribas*, or strongly-fenced stations, established at convenient strategical points for the purpose of raiding the surrounding lands in quest of ivory and the men required to convey it to the coast, where they were sold as slaves. Hence since the partition of Africa these Arabs, mostly half-breeds, have been cleared out, and the stations transformed to centres of European trade and cultural influences. Thus it happens that in the Congo and Zambezi regions there is but a slight strain of Arab blood, whereas throughout the northern half of the continent Semitic elements are in many places grafted on the original Hamitic and Negritic stocks.

The Moslem Semites were accompanied and even preceded by others, the *Jews* of Palestine, who, however, were nearer akin to their Phœnician forerunners than to the Arabs and Himyarites. They began to arrive probably soon after the Babylonian captivity, and considerable numbers were already settled in Lower Egypt under the Ptolemies. After the fall of Jerusalem and the suppression of the subsequent revolts these were joined by others, many of whom passed westwards and settled in all the large towns and surrounding districts, from Tripoli to Morocco, where, despite ages of oppression, they still form numerous wealthy communities. But, living mostly apart, they have scarcely disturbed the ethnical relations in Africa to any appreciable extent.

The same is true also of the still later immigrants from Europe into the northern and southern extra-tropical zones—*Greeks*, *Italians*, *French*, *Spaniards*, in Egypt and Mauritania, *Dutch* and *British*, with some French and Germans, south of the Zambezi. These intruders have given rise to dislocations and displacements, but not to interminglings, with the notable exception of the early Dutch Boers, from whose alliance with the Hottentots have sprung the so-called "Bastards," *i.e.*, *Griquas*, *Gonaquas*, and several other half-caste Hottentot groups in Cape Colony and Namaqualand. Both in the Cape and in Natal are several communities of Mohammedan Malays from various parts of the Eastern Archipelago, while numerous Banians (Hindus of the trading caste) are settled in all the coast towns from Durban to Mombasa. Subjoined is a table of all the African populations, indigenous and intruders, from ancient to present times, as far as known:—

A. CAUCASIC DIVISION.

I. EASTERN HAMITES:—

Retu, ancient Egyptians; later Copts and Fellahin (mixed), Nile valley from 1st cataract to the Delta.
Blemmyes; Bugaitæ, now Begas, Bejas; Ababdeh; Hadendowa; Bishari; Beni-Amer, from Nile to Red Sea between Egypt and Abyssinia.

Athagao, Agao, Agaomedir ("Agaoland") and other parts of Abyssinia.
Afar (Danakil), between Abyssinia, Red Sea, and Gulf of Aden.
Somali; *Gallas*; Somali and Galla lands.
Turkana; *Rendileh*; Lake Rudolf district.
Masai; *Wakwafi*; Mau plateau between Great Rift-Valley and Lake Victoria.
Wahuma, intermingled with the Bantus in the equatorial lake region.

II. WESTERN HAMITES:—

Mahurim ("Westerns"), so called by the Carthaginians, whence Mauri, "Moors," call themselves *Imazighen*, "Freemen"; Maziges, Numidæ, Gætuli, Leucæthiopes, all now known as "Berbers"; Shellalas (Shluhs) of the western Atlas; Kabyles of North Morocco and Algeria; Shawiahs, Zenagas, Beni-Mzabs of Algeria and Tunisia; Haratin ("Black Berbers") of the southern Atlas; Tuaregs of the western Sahara.
Tamahu (*Libyans*), Nasomones; Aujilas; Hammonii; Siwahs, Cyrenaica and Siwah oasis.
Garamantes, *Tedamansi*, Tedas and Dazas (northern and southern *Tibbus*), Tibesti range and the oases of the eastern Sahara.

III. SEMITES:—

Himyarites, Axumites; Tigrifias; Amharifias; Shoas; north, central, and south Abyssinia.
Phœnicians, Carthage and Mauritanian coast lands (extinct).
Arabs (mostly Bedouins), Egypt, Anglo-Egyptian Sudan, Tripolitana, Mauritania, western Sahara, central Sudan, east coast southwards to Sofala.
Jews, Egypt, Tripolitana, Mauritania.

IV. EUROPEANS:—

Hellenes, Cyrenaica, Nile Delta (extinct).
Romans } Africa Provincia, Mauritania (extinct).
Vandals }
Modern Greeks, Egypt, Anglo-Egyptian Sudan.
Maltese }
Italians } Egypt, and thence to Morocco; Canary Islands
French } (Spaniards).
Spaniards }
Dutch, *Huguenots* (extinct), Cape Colony, Natal, the late Boer States.
Britons, Cape, Natal, late Boer States, North and South Rhodesia, Nyasaland, East and West Coast sporadically.
Germans, The Cape, Transvaal, elsewhere sporadically.
Portuguese, East and West Coasts, São Thomé, Cape Verde Islands, Madeira, Azores.

B. NEGRITIC DIVISION.

- I. SUDANESE NEGROES } Full details in Art. NEGRO.
- II. BANTU NEGROIDS }
- III. BUSHMEN, formerly ranged from Tanganyika to the Cape, now mainly confined to the Kalahari Desert (Art. BUSHMEN).
- IV. HOTTENTOTS (Khoi-Khoi):—
Namaqua, Great and Little Namaqualand.
Koraqua, Upper Orange and Vaal rivers.
Griqua, Griqualand East.
Gonaqua, Cape Colony, Eastern Provinces.
 All except the Namaqua are Dutch-Hottentot or Bantu-Hottentot half-breeds.
- V. NEGRITORS:—
Danga (*Tank*) in Egypt from Shade-land beyond Punt (Somaliland) 3300 B.C.
Akkas }
Wochuas } Welle, Aruwimi and Semliki river valleys.
Achuas }
Wambutti }
Dumes } South Gallaland, Lake Rudolf district, Masal-
Dokos } land.
Wandorobos }
Babinga, Middle Sangha, northern tributary, Congo.
Batwa, Sankuru river, southern tributary, Congo.
Abongo, Akoa (Okoa), Okande district, Ogway basin.
Obongo, Ashiraland, Ogway basin.
Vaalpens, Middle Limpopo river, North Transvaal.

(A. H. K.)

III. RECENT POLITICAL HISTORY.

Africa is the last of the continents to be annexed by the nations of Europe, and the process of annexation presents many features which have no parallel in the previous history of the relations of the white with the coloured races. Until 1875 Europe had concerned herself

politically mainly with the northern and southern extremities of the continent, and with a narrow strip along the eastern and western seaboard. There were vast areas in the interior which were still unexplored, but the explorer had penetrated far beyond the limits of European political influence, and in 1875 the explorer did not necessarily include a batch of ready-made treaties among his outfit. It would be interesting to discuss the causes which have, directly or indirectly, led to the extraordinary activity which the Great Powers of Western Europe have displayed in annexing and marking out spheres of influence in the African continent. But such an inquiry would involve a review of the whole field of European politics, and it must be sufficient, before proceeding to a recapitulation of the steps by which Europe has absorbed Africa, to indicate one or two of the main factors in the situation. The Franco-German war of 1870 must be regarded as the real starting-point in the movement. From that war Germany emerged strong and united, eager for new worlds to conquer. France, after the first shock of despair had passed away, began to develop fresh stores of reserve energy, and her statesmen and people, half unconsciously at first, but later of set design, sought to find outside Europe compensation for her lost provinces on the Rhine. France and Germany were both, therefore, ripe for a policy of colonial expansion, and a rapid survey of the land-massés of the globe made it clear that Africa, alone among the continents, offered adequate opportunities for satisfying this new-born land hunger. France still possessed some remnants of her former colonial possessions, and in Northern Africa, and on the Atlantic seaboard, had a firm foothold on the continent. Germany was entirely without colonies, either in Africa or elsewhere. The more temperate regions of the earth had already been acquired by the colonizing Powers that were earlier in the field, and the more accessible parts of the tropics had also been earmarked as British, Dutch, Spanish, or Portuguese. Africa alone, therefore, offered any large field for the resuscitated energies of France, or the virgin activities of Germany; and the history of the modern partition of Africa is mainly a record of the struggles of these two Powers and of Great Britain to secure for themselves as large a share as possible of the continent. The part played by Leopold II., King of the Belgians, in the founding of the Congo Free State, and in the opening up of the continent to the political influence of Europe, furnishes a remarkable episode in that history; but France, Germany, and Great Britain are the principal actors in the drama, and in following the various stages in the work of partition it is necessary, for a proper understanding of the part which each of these three Powers played, to remember that France was the first consciously to recognize the magnitude of the undertaking and the need for speed in its accomplishment; that, in Germany, Prince Bismarck, at the instigation of a small but influential body of "Kolonial-Menschen," took the first steps in the direction of colonial expansion, not only in advance of German public opinion, but before other countries, or at least Great Britain, had realized that Germany was seriously entering the lists as a colonial Power; and finally that Great Britain, though more favourably placed than either of her rivals, was, from a variety of causes, the last to realize the need for action and the urgency of the situation.

The position of Great Britain requires a few words of explanation. She was already in possession of a vast colonial empire, widely distributed over the globe. It was a favourite conception of the public men of the middle half of the 19th century that colonies were quite as much a burden as a blessing, and that, at no very remote period, the young communities which had settled in distant lands

under the British flag would shake themselves free from the control of the mother-country, and begin an independent existence, as soon as they felt themselves able to walk alone. There was a strong disinclination to increase Great Britain's commitments abroad, and in Africa the repeated solicitations of native kings and chiefs in the neighbourhood of British settlements, to be taken under British protection, were rejected in pursuance of a deliberately adopted policy. In 1865 a strong representative committee of the House of Commons unanimously resolved "that all further extension of territory or assumption of government, or new treaty offering any protection to native tribes, would be inexpedient." But while the overtures of native kings were rejected, the fact that they were made, coupled with the further fact that the exploration of the continent had been mainly undertaken by British subjects, or under British auspices, gave rise to the feeling that, in some not very clearly defined way, Great Britain had a sort of vague claim over regions, which, if they were not British, were not claimed by any other European Power. It was not until France had fairly entered on her career of annexation in West Africa, and Germany had entered the field, that the British Government and the British public awoke to the consciousness of the fact that there was no time to be lost if Great Britain was to take her part in the "scramble."

A brief survey of the political situation, and of the position of the European Powers in Africa, at the beginning of the last quarter of the 19th century, will form a fitting prelude to the history of the modern partition of the continent. In 1875 Egypt was under the rule of Ishmaïl Pasha, who had, two years before, been granted by the Sultan the right of concluding treaties with foreign Powers and of maintaining armies. The Khedive's troops had by this time pushed their way southwards along the Nile valley, and had established Egyptian rule in Darfur and Kordofan, while Egyptian influence may be said to have extended right up to the Albert Nyanza. Tripoli was then, as now, a province of the Turkish empire. Morocco, then as now, was an independent state, while Algeria, which had been conquered by France in the second quarter of the century, had been for four years under civil administration so far as the coast regions were concerned, though military rule was still maintained in the interior, and the Saharan tribes did not recognize French authority in any form. On the west coast France had, since the 17th century, been settled at the mouth of the Senegal river, and had made successive advances into the interior towards the valley of the Upper Niger. On the coast her influence was recognized by treaty, from Cape Blanco to the British settlements on the Gambia, and a considerable region had been brought under some sort of administrative control. Below the Gambia France touched the coast again at Casamance, and had extended her influence for some distance towards the interior. On the Ivory Coast France had acquired vague rights, which were turned to good account in the subsequent scramble at Grand Bassam and Assinie, but in 1875 she had taken no practical steps to occupy and administer even these isolated points. The same observation applies to Porto Novo, where France had acquired some sort of footing which enabled her to lay the foundation of her present colony of Dahomey. Farther down the coast the French had establishments at the estuary of the Gabun and on the Ogowé river, but M. Savorgnan de Brazza had not yet begun the work of founding the French Congo Colony. Save for the islands of Réunion, St Marie, Mayotte, and Nossi-Bé, and for the port of Obok, near the southern entrance to the Red Sea—which had been acquired by purchase in 1862, though it was not

effectively occupied till 1883—this exhausts the list of French possessions in Africa in 1875.

Spanish possessions in Africa at the same date consisted of the Canary Islands, an old fort on the Rio d'Oro, —on the ownership of which Spain subsequently based claims to the stretch of coast between the southern limits of Morocco and France's Senegambian possessions, extending from Cape Bojador to Cape Blanco, a distance of some 500 miles,—the island of Fernando Po in the Gulf of Guínea, and a small strip of territory on the banks of the Muni river, which was also claimed by France.

The position of Portugal in Africa in 1875 is very difficult to define. The glorious record of the Portuguese in the exploration of the continent cannot be recapitulated here. But on the strength of her achievements in the past Portugal put forward claims which were as vague as they were extensive, and which the other European Powers interested in Africa firmly refused to recognize. Compared with the claims which she subsequently made, the area of African territory which was actually administered by Portugal in 1875 was ludicrously small. Apart from her island possessions Portugal had a small settlement on the Guinea Coast, south of the French settlement of Casamance, another small settlement at Kabinda, north of the estuary of the Congo, and more extensive possessions south of that river, constituting the provinces of Loanda, Benguela, and Mossamedes. On the east of the continent the Portuguese were settled at Sofala, Mozambique, and other parts of the coast, but their administration was sunk in lethargy, and it is impossible to say, with any approach to accuracy, what were the limits within which they exercised any effective supervision. It was, however, in 1875 that Marshal MacMahon, the then President of the French Republic, settled the long-standing dispute between Great Britain and Portugal for the possession of Delagoa Bay in favour of the latter Power.

In 1875 Great Britain was without question, both as regards the area and the importance of her possessions, the European Power most considerably interested in Africa. But her interests were not confined to territorial rights. British explorers, missionaries, and traders had established British "influence" in various regions of the continent, without obtaining, and in some cases without seeking, Government sanction. For this apparent slackness in regularizing British interests by formal engagements there were two reasons. In the first place the home Government, acting in pursuance of the resolution of 1865, was unwilling to extend the area of its obligations; and in the second place, except in West Africa, where France had shown considerable activity, little or no fear was entertained of the competition of other European Powers. Native chiefs, in many parts of the continent which are now included in non-British spheres of influence, petitioned for British protection; but their requests were refused, partly because of an unwillingness to extend responsibilities beyond the coast, and partly because it was assumed that Great Britain could at any moment take formal possession, should it suit her purpose to do so. In this way British influence "predominated" on the Niger and in the Sultanate of Zanzibar, but in neither case had that predominating influence found formal expression, and when the scramble suddenly began, intruding rivals forced Great Britain to defend her position, which she was only able to make good by considerable sacrifices. At the beginning of the last quarter of the 19th century Great Britain had in fact no recognized footing on the eastern mainland of the African continent north of Natal, the area of which colony was at that period estimated at less than 12,000 square miles. To the north of Natal, along the coast, Zululand was still independent. South

of Natal, Pondoland was also independent, and there were other isolated patches of territory which had not been brought under British rule; but with these comparatively unimportant exceptions the whole of the southern end of the continent, up to the Orange river and the Orange Free State, was British. Basutoland had been annexed in 1868, and three years later had been added to Cape Colony. In 1875 the estimated area of Cape Colony, including British Kaffraria and Basutoland, was 201,000 square miles. Between the Orange river and the Vaal was the Orange Free State, and farther to the north the Transvaal was still an independent republic. On the west coast of Africa Great Britain's possessions were little more than coast settlements, with more or less ill defined relations with the tribes of the interior, established for purposes of trade rather than of administration. Passing up the west coast from the Orange river, the first British territory reached was, in 1875, the Gold Coast Colony, which included the island of Lagos and a strip of the adjacent coast land, as well as the British settlements on the Gold Coast proper. Four years previously, in 1871, the possessions of Great Britain on the coast had been extended by the transfer, for a money consideration, of the Dutch settlements to Great Britain, but even so British authority did not extend any considerable distance from the coast, and the whole area of the Gold Coast settlements proper was roughly estimated at some 6000 square miles. Still farther round the coast was the then still smaller colony of Sierra Leone, and still farther to the north was the last of the West African settlements, on the Gambia river, at that time estimated to have an area of only 21 square miles.

Neither Germany nor Italy had at this time set foot on the continent, nor had the Congo Free State begun to take shape in the mind of its founder. Besides the independent states already named, there were Abyssinia in the north-east; the Sultanate of Zanzibar and Pemba, and a large tract of territory on the mainland with no very clearly defined boundaries; and on the west coast the negro republic of Liberia, which had been established in 1820 as an experiment by the Washington Colonization Society, and had been recognized as an independent state by the European Powers in 1847.

Such, in brief outline, was the political condition of Africa in 1875. In the interior, much of which was either wholly unknown or but very imperfectly known to Europeans, there were considerable native kingdoms, but the materials for fixing their limits at any given moment are extremely scanty, and in dealing with the partition of Africa among the Powers of Europe it is unnecessary to attempt to describe the political condition of the interior of the continent. It may, however, be useful before proceeding further to attempt to tabulate the political position in continental Africa in 1875, for the purpose of comparison with the subsequent table showing the partition of the continent in 1900. It must be borne in mind that the figures given are in almost all cases approximate, and have little positive value in themselves:—

POSITION IN 1875.		Area in sq. miles.
GREAT BRITAIN—		
Cape Colony		201,000
Griqualand West		17,800
Natal		11,172
Lagos		5,000
Gold Coast		6,000
Sierra Leone		468
Gambia		21
Total British Africa		241,461

		Area in sq. miles.
FRANCE—		
Algeria		150,500
Senegambia		10,000
Guinea Coast and Gabun		7,750
Total French Africa		168,250
PORTUGAL—		
Senegambia and Guinea		1,687
Angola		14,700
Mozambique		18,000
Total Portuguese Africa		34,387
SPAIN—		
Ceuta, &c.,		3
Muni river settlements		850
Total Spanish Africa		853
NON-EUROPEAN STATES—		
Transvaal		110,000
Orange Free State		49,000
Liberia		14,300
Egypt and Sudan		1,406,250
Tunis		42,000
Morocco		219,000
Abyssinia }		No estimate.
Zanzibar }		

Many circumstances had combined to arouse the interest of Europe in the hitherto neglected continent of Africa. Narratives of travel by such men as Rebmann, Krapf, Burton, Speke and Grant, Schweinfurth, Nachtigal, Livingstone, and Stanley, had stimulated interest outside geographical circles. Livingstone's tragic death in the heart of the continent, and Stanley's letters from Uganda, where he arrived in April 1875, had aroused the enthusiasm of the missionary societies, while the importance of finding new markets was turning the thoughts of the manufacturing and trading classes to the possibility of Africa as a centre of commercial enterprise. The psychological moment had arrived, and with it the man who was to shape these inchoate forces to a definite end. Leopold, King of the Belgians, the sovereign of one of the smallest states of Europe, found in the narrow limits of his kingdom an insufficient field for his restless energies and ambitions. He had travelled in the Far East, and had entertained thoughts of founding a colony in that part of the world. But Africa fascinated him as it did so many less distinguished personages. The vast area of the almost virgin continent offered an apparently illimitable field, both for scientific exploration and for commercial development; and in September 1876 King Leopold took what may be described as the first definite step in the modern partition of the continent. He summoned to a conference at Brussels representatives of Great Britain, Belgium, France, Germany, Austria-Hungary, Italy, and Russia, to deliberate on the best methods to be adopted for the exploration and civilization of Africa, and the opening up of the interior of the continent to commerce and industry. The conference was entirely unofficial. The delegates who attended neither represented nor pledged their respective Governments. Their deliberations lasted three days, and resulted in the foundation of "The International African Association," with its headquarters at Brussels. It was further resolved to establish national committees in the various countries represented, which should collect funds and appoint delegates to the International Association. The central idea appears to have been to put the exploration and development of Africa upon an international footing. But it quickly became apparent that this was an unattainable ideal. The national committees were soon working independently of the International Association, and the Association itself passed through a succession of stages until it became purely Belgian in character, and at last developed

into the Congo Free State, under the personal sovereignty of King Leopold. At first the Association devoted itself to sending expeditions to the great central lakes from the east coast; but failure, more or less complete, attended its efforts in this direction, and it was not until the return of Stanley from his great journey down the Congo in January 1878, that its ruling spirit, King Leopold, definitely turned his thoughts towards the Congo. In June of that year, Mr Stanley visited the king at Brussels, and in the following November a private conference was held, and a committee was appointed for the investigation of the Upper Congo.

Mr Stanley's remarkable discovery had stirred ambition in other capitals than Brussels. France had always taken a keen interest in West Africa, and in the years 1875 to 1878 M. Savorgnan de Brazza had carried out a successful exploration of the

Stanley and the Congo.

Ogowé river to the south of the Gabun. M. de Brazza determined that the Ogowé did not offer that great waterway into the interior of which he was in search, and he returned to Europe without having heard of the discoveries of Mr Stanley farther south. Naturally, however, Mr Stanley's discoveries were keenly followed in France. In Portugal, too, the discovery of the Congo with its magnificent unbroken waterway of more than a thousand miles into the heart of the continent, served to revive the languid energies of the Portuguese, who promptly began to furbish up claims whose age was in inverse ratio to their validity. Claims, annexations, and occupations were in the air, and when in January 1879, Mr Stanley left Europe as the accredited agent of King Leopold and the Congo committee, the strictest secrecy was observed as to his real aims and intentions. The expedition was, it was alleged, proceeding up the Congo to assist the Belgian expedition which had entered from the east coast, and Mr Stanley himself went first to Zanzibar. But in August 1879 Mr Stanley found himself again at Banana Point, at the mouth of the Congo, with, as he himself has written, "the novel mission of sowing along its banks civilized settlements to peacefully conquer and subdue it, to remould it in harmony with modern ideas into national states, within whose limits the European merchant shall go hand in hand with the dark African trader, and justice and law and order shall prevail, and murder and lawlessness and the cruel barter of slaves shall be overcome." The irony of human aspirations was never perhaps more plainly demonstrated than in the contrast between the ideal thus set before themselves by those who employed Mr Stanley, and the actual results of their intervention in Africa. Mr Stanley founded his first station at Vivi, between the mouth of the Congo and the rapids that obstruct its course where it breaks over the western edge of the central continental plateau. Above the rapids he established a station on Stanley Pool and named it Leopoldville, founding other stations on the main stream in the direction of the falls that bear his name.

Meanwhile M. de Brazza was far from idle. He had returned to Africa towards the end of the same year which saw Stanley back on the Congo, and while the agents of King Leopold were making treaties and founding stations along the southern bank of the river, M. de Brazza and other French agents were equally busy on the northern bank. M. de Brazza was sent out to Africa by the French committee of the International African Association, which provided him with the funds for the expedition. His avowed object was to explore the region between the Gabun and Lake Chad. But there is not much doubt that his real object was to anticipate Mr Stanley on the Congo. The international character of the association

French rivalry.

founded by King Leopold was never more than a polite fiction, and the rivalry between the French and the Belgians on the Congo was soon open if not avowed. In October 1880 M. de Brazza made a solemn treaty with a chief on the north bank of the Congo, who claimed that his authority extended over a large area, including territory on the southern bank of the river. As soon as this chief had accepted French protection, M. de Brazza crossed over to the south of the river, and founded a station close to the present site of Leopoldville. The discovery of the French station by Mr Stanley naturally annoyed King Leopold's agent, and he promptly challenged the rights of the chief who purported to have placed the country under French protection, and himself founded a Belgian station close to the site selected by M. de Brazza. In the result, the French station was withdrawn to the northern side of Stanley Pool, where it is now known as Brazzaville.

The activity of French and Belgian agents in the Congo had not passed unnoticed in Lisbon, and the Portuguese Government saw that no time was to be lost if the claims it had never ceased to put forward on the west coast were not to go by default. At varying periods during the 19th century Portugal had put forward claims to the whole of the West African coast, between 5° 12' and 8° south latitude. North of the Congo mouth, she claimed the territories of Kabinda and Molemba, alleging that they had been in her possession since 1484. Great Britain had never, however, admitted this claim, and south of the Congo had declined to recognize Portuguese possessions as extending north of Ambriz. In 1856 orders were given to British cruisers to prevent by force any attempt to extend Portuguese dominion north of that place. But the Portuguese had been persistent in urging their claims, and in 1882 negotiations were again opened with the British Government for recognition of Portuguese rights over both banks of the Congo on the coast, and for some distance inland. Into the details of the negotiations, which were conducted for Great Britain by Lord Granville, who was then Secretary for Foreign Affairs, it is unnecessary to enter; they resulted in the signing on the 26th February 1884 of an agreement, by which Great Britain recognized the sovereignty of the king of Portugal "over that part of the west coast of Africa, situated between 8° and 5° 12' south latitude," and inland as far as Nokki, on the south bank of the Congo, below Vivi. The navigation of the Congo was to be controlled by an Anglo-Portuguese commission. The publication of this treaty evoked immediate protests, not only on the Continent, but in Great Britain. In face of the universal disapproval aroused by the agreement, Lord Granville found himself unable to ratify it. The protests had not been confined to France and the King of the Belgians. Germany had not yet acquired formal footing in Africa, but she was crouching for the spring prior to taking her part in the scramble, and Prince Bismarck had expressed, in vigorous language, the objections entertained by Germany to the Anglo-Portuguese agreement.

Portuguese claims.

For some time before 1884 there had been growing up a general conviction that it would be desirable, for the Powers who were interesting themselves in Africa, to come to some agreement as to "the rules of the game," and to define their respective interests so far as that was practicable. Lord Granville's ill-fared treaty brought this sentiment to a head, and it was agreed to hold an international conference on African affairs. But before discussing the Berlin Conference of 1884-85, it will be well to see what was the position, on the eve of the conference, in other parts of the African continent. In the southern section of Africa, south of the Zambezi, impor-

tant events had been happening. In 1876 Great Britain had concluded an agreement with the Orange Free State for an adjustment of frontiers, the result of which was to leave the Kimberley diamond fields in British territory, in exchange for a payment of £90,000 to the Orange Free State. On the 12th April 1877, Sir Theophilus Shepstone had issued a proclamation declaring the Transvaal—the South African Republic, as it was formerly designated—to be British territory. (See *TRANSVAAL*.) On the 29th September 1879, Sir Garnet Wolseley, the commander-in-chief in South Africa, issued another proclamation, declaring the Transvaal to be for ever an integral portion of the British dominions in South Africa. In December 1880 war broke out, and lasted until March 1881, when a treaty of peace was signed. This treaty of peace was followed by a convention, signed in August of the same year, under which complete self-government was guaranteed to the inhabitants of the Transvaal, subject to the suzerainty of Great Britain, upon certain terms and conditions and subject to certain reservations and limitations. No sooner was the convention signed than it became the object of the Boers to obtain a modification of the conditions and limitations imposed, and in February 1884 a fresh convention was signed, amending the convention of 1881. Article IV. of the new convention provided that “The South African Republic will conclude no treaty or engagement with any state or nation other than the Orange Free State, nor with any native tribe to the eastward or westward of the Republic, until the same has been approved by Her Majesty the Queen.” The precise effect of the two conventions has been the occasion for interminable discussions, but as the subject is now one of merely academic interest, it is sufficient to say that when the Berlin Conference held its first meeting in 1884 the Transvaal was practically independent, so far as its internal administration was concerned, while its foreign relations were subject to the control just quoted. As early as 1875, in a protocol attached to a treaty of friendship, commerce, and boundaries, between the Transvaal and Portugal, an agreement had been made for the construction of a line between Delagoa Bay and Pretoria; and in 1884 a further agreement was made between the same parties to the same effect, both agreements receiving the sanction of Queen Victoria as suzerain.

But although the Transvaal had thus, between the years 1875-84, become and ceased to be British territory, British influence in other parts of Africa south of the Zambezi had been steadily extended. To the west of the Orange Free State, Griqualand West was annexed to the Cape in 1877, while to the east the territories beyond the Kei river were included in Cape Colony between 1877 and 1884, so that in the latter year, with the exception of Pondoland, the whole of South-East Africa up to Natal was in one form or another under British control. North of Natal, Zululand was not actually annexed until 1887, although since the 1879 war, and the restoration of Cetewayo in 1882, British influence had been admittedly supreme. In December 1884 St Lucia Bay had been proclaimed a British possession, and three years later an agreement of non-cession to foreign powers made by Great Britain with the regent and paramount chief of Tongaland, completed the chain of British possessions on the coast of South Africa, from the mouth of the Orange river on the west to Kosi Bay and the Portuguese frontier, on the east. In the interior of South Africa, the year 1884 witnessed the beginning of that final stage of the British advance towards the north which was eventually to extend British influence from the Cape to the southern shores of Lake Tanganyika. The activ-

ity of the Germans on the west, and of the Boer republic on the east, had brought home to both the imperial and colonial authorities the impossibility of relying on vague traditional claims. In May 1884 treaties were made with native chiefs by which the whole of the country north of Cape Colony, west of the Transvaal, south of 22° S. latitude, and east of 20° E. longitude was placed under British protection, though a protectorate was not formally declared until the following January. The southern portion of this newly-acquired territory up to the Molopo river was in September 1875, under the name of British Bechuanaland, placed under the jurisdiction of the governor of Cape Colony, while the territory north of the Molopo river and south of 22° S. latitude, which included Khama's country, Bathoen's country, Sebele's country, and the Kalahari desert, was at the same time declared a British protectorate, the local administration being left in the hands of the native chiefs.

Meanwhile some very interesting events had been taking place on the west coast, north of the Orange river, and south of the Portuguese province of Mossamedes. In Germany a variety of circumstances had conspired to turn the thoughts of both the rulers and the ruled towards the acquisition of territories overseas, where German colonists could settle under the German flag. It must be sufficient here to touch very briefly on the events that preceded the foundation of what is now the colony of German South-West Africa. For many years prior to 1884, German missionaries had settled among the Damaras and Namaquas, often combining small trading operations with their missionary work. From time to time trouble arose between the missionaries and the native chiefs, and appeals were made to the German Government for protection. The German Government in its turn begged the British Government to say whether it assumed responsibility for the protection of Europeans in Damaraland and Namaqualand. The position of the British Government was intelligible, if not very intelligent. It did not desire to see any other European Power in these countries, and it did not want to assume the responsibility and incur the expense of protecting the few Europeans settled there. Sir Bartle Frere, when Governor of the Cape (1877-81), had foreseen that this attitude portended trouble, and had urged that the whole of the unoccupied coast-line, up to the Portuguese frontier, should be declared under British protection. But he preached to deaf ears, and it was as something of a concession to him that in March 1878 the British flag was hoisted at Walfisch Bay, and the country for a radius of 15 miles was declared to be British. The fact appears to be that British statesmen failed to understand the change that had come over Germany. They believed that Prince Bismarck would never give his sanction to the creation of a colonial empire, and, to the German inquiries as to what rights Great Britain claimed in Damaraland and Namaqualand, procrastinating replies were sent. Meanwhile the various colonial societies established in Germany had effected a revolution in public opinion, and, more important still, they had convinced the great Chancellor. Accordingly when, in November 1882, Herr Lüderitz, a Bremen merchant, informed the German Government of his intention to establish a factory on the coast between the Orange river and the Little Fish river, and asked if he might rely on the protection of his Government in case of need, he met with no discouragement from Prince Bismarck. In February 1883 the German ambassador in London informed Lord Granville of Herr Lüderitz's design, and asked “whether Her Majesty's Government exercise any authority in that locality.” It was intimated that if Her Majesty's Gov-

*Germany
in South-
West
Africa.*

ernment did not, the German Government would extend to Herr Lüderitz's factory "the same measure of protection which they give to their subjects in remote parts of the world, but without having the least design to establish any footing in South Africa." An inconclusive reply was sent, and on the 9th April Herr Lüderitz's agent landed at Angra Pequena, and after a short delay concluded a treaty with the local chief, by which some 215 square miles around Angra Pequena Bay was ceded to Herr Lüderitz. In England and at the Cape irritation at the news was mingled with incredulity, and it was fully anticipated that Herr Lüderitz would be disavowed by his Government. But for this belief, it can scarcely be doubted that the rest of the unoccupied coast-line would have been promptly declared under British protection. In the month of August the German Government intimated to their consular representative at the Cape their preparedness to take Herr Lüderitz's concessions under the protection of the Imperial Government. In November the German ambassador again inquired if Great Britain made any claim over this coast, and Lord Granville replied that Her Majesty exercised sovereignty only over certain parts of the coast, as at Walfisch Bay, and suggested that arrangements might be made by which Germany might assist in the settlement of Angra Pequena. By this time Herr Lüderitz had extended his acquisitions southwards to the Orange river, which had been declared by the British Government to be the northern frontier of Cape Colony. Both at the Cape and in England it was now realized that Germany had broken away from her former purely Continental policy, and, when too late, the Cape parliament showed great eagerness to acquire the territory which had lain so long at its very doors, to be had for the taking. It is not necessary to follow the course of the subsequent negotiations. On the 15th August 1884 an official note was addressed by the German consul at Capetown to the High Commissioner, intimating that the German Emperor had by proclamation taken "the territory belonging to Mr A. Lüderitz on the west coast of Africa under the direct protection of His Majesty." This proclamation covered the coast-line from the north bank of the Orange river to 26° S. latitude, and 20 geographical miles inland, including "the islands belonging thereto by the law of nations." On the 8th of the following month—September 1884—the German Government intimated to Her Majesty's Government, "that the west coast of Africa from 26° S. latitude to Cape Frio, excepting Walfisch Bay, had been placed under the protection of the German Emperor." Thus, before the end of the year 1884, the foundations of Germany's colonial empire had been laid in South-West Africa.

In April of that year Prince Bismarck intimated to the British Government, through the German chargé d'affaires in London, that "the Imperial consul-general,

West Africa.

Dr Nachtigal, has been commissioned by my Government to visit the west coast of Africa in the course of the next few months, in order to complete the information now in the possession of the Foreign Office at Berlin, on the state of German commerce on that coast. With this object Dr Nachtigal will shortly embark at Lisbon, on board the gunboat *Möwe*. He will put himself into communication with the authorities in the British possessions on the said coast, and is authorized to conduct, on behalf of the Imperial Government, negotiations connected with certain questions. I venture," the official communication proceeds, "in accordance with my instructions, to beg your excellency to be so good as to cause the authorities in the British possessions in West Africa to be furnished with suitable recommendations." Although at the date of this communication it

must have been apparent, from what was happening in South Africa, that Germany was prepared to enter on a policy of colonial expansion, and although the wording of the letter was studiously vague, it does not seem to have occurred to the British Government that the real object of Dr Nachtigal's journey was to make other annexations on the west coast. Yet such was indeed his mission. German traders and missionaries had been particularly active of late years on the coast of the Gulf of Guinea. German factories were dotted all along the coast in districts under British protection, under French protection, and under the definite protection of no European Power at all. It was to these latter places that Dr Nachtigal turned his attention. The net result of his operations was that on the 5th July 1884 a treaty was signed with the King of Togo, placing his country under German protection, and that just one week later a German protectorate was proclaimed over the whole of the Cameroon district. Before either of these events had occurred Great Britain had become alive to the fact that she could no longer dally with the subject, if she desired to consolidate her possessions in West Africa. The British Government had again and again refused to accord native chiefs the protection they demanded. The Cameroon chiefs had several times asked for British protection, and always in vain. But at last it became apparent, even to the official mind, that rapid changes were being effected in Africa, and on the 16th May Consul Hewett received instructions to return to the west coast and to make arrangements for extending British protection over certain regions. He arrived too late to save either Togoland or Cameroon, in the latter case arriving five days after King Bell and the other chiefs on the river had signed treaties with Dr Nachtigal. But the British consul was in time to secure the delta of the river Niger and the Oil Rivers District, extending from Rio del Rey to the Lagos frontier, where for a long period British traders had held almost a monopoly of the trade. Meanwhile France, too, had been busy treaty-making. During the year 1884 no less than forty-two treaties were concluded with native chiefs, an even larger number having been concluded in the previous twelve months. While the British Government still remained under the spell of the fatal resolution of 1865, the French Government was strenuously endeavouring to extend France's influence in West Africa, in the countries lying behind the coast-line. In the campaign of 1880-81 Captain Gallieni advanced as far as Bamako, on the Upper Niger, and other French officials were steadily pursuing the policy which has resulted in surrounding all the old British possessions in West Africa with a continuous band of French territory. In 1881 a preliminary step was taken in a project which, still unrealized, has always exercised a strange fascination over that section of public opinion in France which mostly concerns itself with African affairs. To join France's possessions on the Mediterranean with her colonies in West Africa, by means of a railway is, with many Frenchmen, a haunting ambition. We need not consider the strategical, political, and commercial arguments which are advanced in favour of the proposed trans-Saharan railway, or discuss the difficulties which surround the accomplishment of this grandiose conception. But, in 1881, an expedition was sent from Algeria to make a preliminary survey and report. It was under the command of Colonel Flatters, and had not advanced very far into the desert before it was attacked by the Tuaregs and massacred.

There was, however, one region on the west coast where, notwithstanding the lethargy of the British Government, British interests were being vigorously pushed, protected,

and consolidated. This was on the Lower Niger, and the leading spirit in the enterprise was Sir George Taubman Goldie. After the discovery of the course of *The Niger.* the Lower Niger in 1829 several expeditions had been undertaken, both by the British Government and by private persons, up the river, but owing to the opposition of the tribes who acted as middlemen between the European traders on the coast and the native traders in the interior, and to the unhealthy climatic conditions, very little progress was made in opening up communication with the inland tribes. Factories were established on the Niger delta and on the Oil Rivers creeks by several trading firms, mostly hailing from Liverpool and Glasgow, but up to the year 1879 nothing was done to secure joint action. In that year the various trading firms on the Lower Niger formed themselves into the "United African Company," and the foundations were laid of something like settled administration. An application was made to the British Government for a charter in 1881, and the capital of the company increased to a million sterling. Henceforth the company was known as the "National African Company," and it was acknowledged that its object was not only to develop the trade of the Lower Niger, but to extend its operations to the middle reaches of the river, and to open up direct relations with the great Fulah empire of Sokoto and the smaller states associated with Sokoto under a somewhat loosely-defined suzerainty. The great development of trade which followed the combination of British interests carried out under the skilful guidance of Mr Goldie-Taubman (now Sir George Goldie) did not pass unnoticed in France, and, encouraged by Gambetta, French traders made a bold bid for a position on the river. Two French companies, with ample capital, were formed, and various stations were established on the Lower Niger. Sir George Goldie realized at once the seriousness of the situation, and lost no time in declaring commercial war on the new comers. His bold tactics were entirely successful, and a few days before the meeting of the Berlin Conference he had the satisfaction of announcing that he had bought out the whole of the French interests on the river, and that Great Britain alone possessed any interests on the Lower Niger.

To complete the survey of the political situation in Africa, when the plenipotentiaries met at Berlin, it is necessary to refer briefly to the course of events in North and East Africa since 1875. In 1881 the French army entered Tunis, and compelled the Bey to sign a treaty placing that country under French protection. The Sultan of Turkey formally protested against this invasion of Ottoman rights, but the Great Powers took no action, and France was left in undisturbed possession of her newly-acquired territory. In Egypt the joint control exercised by Great Britain and France under the Khedival decree of 10th November 1879 had broken down, owing to the refusal of France to join in the suppression of the Arabi Pasha rebellion, and had been abolished by the decree of 18th January 1883; since which date Great Britain had assumed a predominant position in Egyptian affairs. (See EGYPT.) In East Africa, north of the Portuguese possessions, where the Sultan of Zanzibar was the most considerable native potentate, Germany was secretly preparing the foundations of her present colony of German East Africa. But no overt act had warned Europe of what was impending. The story of the foundation of German East Africa is one of the romances of the continent. Early in 1884 the Society for German Colonization was founded, with the avowed object of furthering the newly-awakened colonial aspirations of the German people. It was a society in-

spired and controlled by young men, and on the 4th November 1884, eleven days before the conference assembled at Berlin, three young Germans arrived as deck passengers at Zanzibar. They were disguised as mechanics, but were in fact Dr Carl Peters the president of the Colonization Society, Joachim Count Pfeil, and Dr Jühlke, and their stock-in-trade consisted of a number of German flags and a supply of blank treaty forms. They proposed to land on the mainland opposite Zanzibar, and to conclude treaties in the back country with native chiefs placing their territories under German protection. The enterprise was frowned upon by the German Government; but, encouraged by German residents at Zanzibar, the three young pioneers crossed to the mainland, and on the 19th November, while the diplomatists assembled at Berlin were solemnly discussing the rules which were to govern the game of partition, the first "treaty" was signed at Mbuguzi, and the German flag raised for the first time in East Africa.

In the period between 1875-84 Italy had also obtained her first footing on the African continent. By a treaty with the sultan of Assab, chief of the Danakils, signed on the 15th March 1883 and subsequently approved by the King of Shoa, Italy obtained the cession of part of Ablis (Aussa) on the Red Sea, Italy undertaking to protect with her fleet the Danakil littoral.

One other event of some importance must further be recorded as happening before the meeting of the Berlin Conference. The King of the Belgians had been driven to the conclusion that, if his African enterprise was to obtain any measure of permanent success, its international status must be recognized. To this end negotiations were opened with various Governments. The first Government to "recognize the flag of the International African Association as the flag of a friendly Government" was that of the United States, its declaration to that effect bearing date the 22nd April 1884. There were, however, difficulties in the way of obtaining the recognition of the European Powers, and in order to obtain that of France, and while labouring under the feelings of annoyance which had been aroused by the Anglo-Portuguese agreement concluded by Lord Granville in February, King Leopold, on the 23rd April 1884, authorized Colonel Strauch, president of the International Association, to engage to give France "the right of preference if, through unforeseen circumstances, the Association were compelled to sell its possessions." France's formal recognition of the Association as a Government was, however, delayed by the discussion of boundary questions until the following February, and in the meantime Germany, Great Britain, Italy, Austria-Hungary, Holland, and Spain had all recognized the Association; though Germany alone had done so—on 8th November—before the assembling of the conference.

The conference assembled at Berlin on 15th November 1884. Its last sitting was held on the 30th January 1885, and the "General Act of the Berlin Conference" was signed by the representatives of all the Powers attending the conference, except the United States, on the 24th February.

The European Powers represented were Great Britain, Germany, Austria-Hungary, Belgium, Denmark, Spain, France, Italy, Holland, Portugal, Russia, Sweden and Norway, and Turkey, to name them in the order adopted in the preamble to the General Act. It is unnecessary to examine in detail the results of the labours of the conference. The General Act dealt with six specific subjects: (1) freedom of trade in the basin of the Congo, (2) the slave trade, (3) neutrality of territories in the basin of the Congo, (4) navigation of the Congo, (5) navigation of the Niger, (6) rules for future occupation on the coasts of the African continent. It will be seen that the

The position in North and East Africa.

The Berlin Conference.

Act dealt with other matters than the political partition of Africa; but, so far as they concern our present purpose, the results effected by the Berlin Act may be summed up as follows. The signatory Powers undertook that any fresh act of taking possession on any portion of the African coast must be notified by the Power taking possession, or assuming a protectorate, to the other signatory Powers. It was further provided that any such occupation to be valid must be effective. It is also noteworthy that the first reference in an international Act of the obligations attaching to "spheres of influence" is contained in the Berlin Act.

The basin of the Congo was defined as "bounded by the watersheds (or mountain ridges) of the adjacent basins, namely, in particular those of the Niari, the *The Congo Free State.* Ogové, the Shari, and the Nile on the north; by the eastern watershed line of the affluents of Lake Tanganyika on the east; and by the watersheds of the basins of the Zambezi and the Logé on the south. It therefore comprises all the regions watered by the Congo and its affluents, including Lake Tanganyika, with its eastern tributaries." In this conventional basin of the Congo the trade of all nations was to enjoy complete freedom. But the free-trade zone was extended considerably beyond the Congo basin. It comprised on the east coast the maritime zone, extended from 2° 30' of S. lat. to the mouth of the Logé. The northern boundary of the free-trade zone followed the parallel of 2° 30' to the geographical basin of the Congo, and thence to the east coast at 5° N. lat., the eastern boundary following the coast southwards to the mouth of the Zambezi; from this latter point the southern boundary followed the Zambezi to 5 miles above its confluence with the Shiré, and thence along the Nyasa-Zambezi watershed to the Congo-Zambezi watershed and the source of the Logé, which it followed to the coast. The approval of independent sovereign states in the eastern zone, which were not parties to the convention, was, however, to be obtained as a condition precedent to the extension of free trade to the eastern zone. The Act contained provisions limiting the dues to be levied within the prescribed area to such as "may be levied as fair compensation for expenditure in the interests of trade," prohibiting the imposition of preferential duties, and declaring the river free to the trading flags of all nations. The conventional basin of the Congo was to remain neutral in all circumstances, and an international navigation commission of the Congo was to be instituted to supervise the carrying out of the principles proclaimed in the General Act on that river and its affluents. No such commission was, however, in fact appointed. The navigation of the Niger and all its affluents was declared free to the merchant vessels of all nations, and Great Britain and France severally undertook to extend protection to traders of other nationalities in those portions of the river which were under their sovereignty or protection.

It will be remembered that when the conference assembled the International Association of the Congo had only been recognized as a sovereign state by the United States and Germany. But King Leopold and his agents had taken full advantage of the opportunity which the conference afforded, and before the General Act was signed the Association had been recognized by all the signatory Powers, with the not very important exception of Turkey, and the fact communicated to the conference by Colonel Strauch. It was not, however, until two months later, in April 1885, that King Leopold, with the sanction of the Belgian legislature, formally assumed the headship of the new state; and on the 1st August in the same year His Majesty notified the Powers that from that date the "Independent State of the Congo" declared that "it shall be perpetually neutral" in conformity with

Article X. of the Berlin Act. Thus was finally constituted the Congo Free State, under the sovereignty of King Leopold, though the boundaries claimed for it at that time were considerably modified by subsequent agreements.

From 1885 the scramble among the Powers went on with renewed vigour, and in the fifteen years that remained of the century the work of partition, so far as international agreements were concerned, *Developments since 1885.* was practically completed. To attempt to follow the process of acquisition year by year would involve a constant shifting of attention from one part of the continent to another, inasmuch as the scramble was proceeding simultaneously all over Africa. It will therefore be the most convenient plan to deal with the continent in sections, roughly corresponding to the quarters of the compass, with the Congo Free State as a sort of central state, the growth of which may serve as the starting-point for the story of the partition after the Berlin Conference. In the notification to the Powers of 1st August 1885, the boundaries of the Free State were set out in considerable detail. The limits thus determined resulted partly from agreements made with France and Portugal, and partly from treaties with native chiefs, and left the northern bank of the Congo to a point a little above Manyanga to the Free State, and the southern bank as far as Nokki to Portugal. The southern frontier was continued along the parallel of Nokki till it intersected the river Kwango, which it followed in a southerly direction. The northern frontier from Manyanga followed the Congo as far as Stanley Pool, then the median line of that pool, leaving the Congo at a point above the Likona-Nkunja river, following its watershed to the 17th degree of longitude east of Greenwich, which degree it followed until its intersection with the 4th parallel of N. latitude, following that latitude until it met the 30th degree of longitude east of Greenwich, which formed the eastern boundary of the Free State. The south-eastern frontier claimed by King Leopold extended to Lakes Tanganyika, Mweru, and Bangweulu, but it was not until some years later that it was recognized and defined by the agreement of May 1894 with Great Britain. The international character of King Leopold's enterprise had not long been maintained, and his recognition as sovereign of the Free State confirmed the distinctively Belgian character which the Association had assumed, even before that event. The king was naturally anxious that the right of pre-emption which he had given to France should not operate against Belgium, and in April 1887 the French Government, in return for territorial concessions on the Mobangi, formally declared that France's right of pre-emption could not be opposed to Belgium's preferential rights; and by his will, dated 2nd August 1889, His Majesty made Belgium heir to the sovereign rights of the Congo Free State. In July 1890 the Free State concluded an agreement with Belgium, by which the Belgian Government agreed to make a loan to the Free State of twenty-five millions of francs, spread over ten years, Belgium acquiring the right within six months after the expiry of that period to annex the Free State. To complete this section of the subject, it may be stated that an annexation Bill, introduced into the Belgian parliament in 1895, was withdrawn, and up to June 1901 Belgium had still taken no formal steps to assume direct responsibility for the Free State as a Belgian colony.

The area of the Free State, vast as it was, did not suffice to satisfy the ambition of its sovereign. King Leopold maintained that the Free State enjoyed, *Aims of the Powers.* equally with any other state, the right to extend its frontiers. As this ambition brought the Free State into sharp conflict with its various European neighbours, it may be well to consider, in the light of

subsequent events, what were at this period the designs entertained by the different European Powers that participated in the struggle for Africa. Portugal was striving to retain as large a share as possible of her shadowy empire, and particularly to establish her claims to the Zambezi region, so as to secure a belt of territory across Africa from Mozambique to Angola. Great Britain, once aroused to the imminence of the danger, put forth vigorous efforts in East Africa and on the Niger, but her most ambitious dream was the establishment of an unbroken line of British possessions and spheres of influence from south to north of the continent, from Cape Colony to Egypt. Germany's ambition can be easily described. It was to secure as much as possible, so as to make up for lost opportunities. French ambitions, apart from Madagascar, were confined to the northern and central portions of the continent. To extend her possessions on the Mediterranean littoral, and to connect them with her colonies in West Africa, the Western Sudan, and on the Congo, by establishing her influence over the vast intermediate regions, was France's first ambition. But the defeat of the Italians in Abyssinia, and the impending downfall of the Khalifa's power in the valley of the Upper Nile, suggested a still more daring project to the French Government—none other than the establishment of French influence over a broad belt of territory stretching across the continent from west to east, from Senegal on the Atlantic coast to Jibuti on the Gulf of Aden. These conflicting ambitions could not all be realized, and Germany succeeded in preventing Great Britain from realizing her ambition of a continuous band of British territory from south to north, while Great Britain, by excluding France from the Upper Nile valley, dispelled the French dream of an empire from west to east.

It was in the struggle between France and Great Britain for the Upper Nile valley that the ambition of

King Leopold and the Nile. King Leopold involved the Congo Free State. The Egyptian Sudan, after the death of Gordon in January 1885, was abandoned to the Mahdi.

The Egyptian frontier was withdrawn to Wady-Halfa, and the vast provinces of Kordofan, Darfur, and the Bahr-el-Ghazal were given over to Dervish tyranny and misrule. But it was obvious that this was not a state of things which could continue indefinitely. Under the wise guidance of Lord Cromer the finances of Egypt had been placed on a sound basis, and under British officers the despised fellaheen had developed soldierly qualities of which they had before given no sign. That Egypt would seek to recover her position in the Sudan was a foregone conclusion, as the command of the Upper Nile was recognized as essential to her continued prosperity. But the international position of the abandoned provinces was by no means clear. The British Government, by the Anglo-German agreement of July 1890, had secured the assent of Germany to the proposition that the British sphere of influence in East Africa was bounded on the west by the Congo Free State and by "the western watershed of the basin of the Upper Nile"; but this claim was not recognized either by France or by the Congo Free State. From her base on the Congo, France was busily engaged pushing forward along the northern tributaries of the great river. On 27th April 1887 an agreement was signed with the Congo Free State by which the right bank of the Mobangi river was secured to French influence, and the left bank to the Congo Free State, with this proviso, that the northern boundary of the Free State was not to descend below the fourth parallel of north latitude. The desire of France to secure a footing in the Upper Nile valley was partly due, as we have seen, to her anxiety to extend a French zone across Africa, but it was also and to a large extent

attributable to the belief, widely entertained in France, that by establishing herself on the Upper Nile France could regain the position in Egyptian affairs which she had sacrificed in 1882. With these strong inducements France set steadily to work to consolidate her position on the tributary streams of the Upper Congo basin, preparatory to crossing into the valley of the Upper Nile. As a step in this direction the Mobangi region was constituted a separate province, under M. Liotard as governor. Meanwhile a similar advance was being made from the Congo Free State northwards and eastwards. King Leopold had two objects in view—to obtain control of the rich province of the Bahr-el-Ghazal and to secure an outlet on the Nile. Stations were established on the Welle river, and in February 1891, Captain van Kerckhoven left Leopoldville for the Upper Welle with the most powerful expedition which had, up to that time, been organized by the Free State. After some heavy fighting the expedition reached the Nile in September 1892, and opened up communications with the remains of the old Egyptian garrison at Wadelai. Other expeditions under Belgian officers penetrated into the Bahr-el-Ghazal, and it was apparent that King Leopold proposed to rely on effective occupation as an answer to any claims which might be advanced by either Great Britain or France. The news of what was happening in this remote region of Africa filtered through to Europe very slowly, but King Leopold was warned on several occasions that Great Britain would not recognize any claims by the Congo Free State on the Bahr-el-Ghazal. The difficulty was, however, that neither from Egypt, whence the road was barred by the Khalifa, nor from Uganda, which was too far removed from the coast to serve as the base of a large expedition, could a British force be despatched to take effective occupation of the Upper Nile valley. There was, therefore, danger lest the French should succeed in establishing themselves on the Upper Nile before the preparations which were being made in Egypt for "smashing" the Khalifa were completed.

In these circumstances Lord Rosebery, who was then foreign minister, began, and his successor, Lord Kimberley, completed, negotiations with King Leopold which resulted in the conclusion of the Anglo-Congolese agreement of 12th May 1894. By this agreement King Leopold recognized the British sphere of influence as laid down in the Anglo-German agreement of July 1890, and Great Britain granted a lease to King Leopold of certain territories in the western basin of the Upper Nile, extending on the Nile from a point on Lake Albert to Fashoda, and westwards to the Congo-Nile watershed. The practical effect of this agreement was to give the Congo Free State a lease, during its sovereign's lifetime, of the old Bahr-el-Ghazal province, and to secure after His Majesty's death a portion of that territory, with access to a port on Lake Albert, to his successor. At the same time the Congo Free State leased to Great Britain a strip of territory, 15½ miles in breadth, between the north end of Lake Tanganyika and the south end of Lake Albert Edward. This agreement was hailed as a notable triumph for British diplomacy. But the triumph was short-lived. By the agreement of July 1890 with Germany, Great Britain had been reluctantly compelled to abandon her hopes of through communication between the British spheres in the northern and southern parts of the continent, and to consent to the boundary of German East Africa marching with the eastern frontier of the Congo Free State. Germany frankly avowed that she did not wish to have a powerful neighbour interposed between herself and the Congo Free State, and later troubles as

The Anglo-Congolese agreement of 1894.

to frontiers in the Lake Kivu region fully justified the attitude of the German Government. It was obvious that the new agreement would effect precisely what Germany had declined to agree to in 1890. Accordingly Germany protested in such vigorous terms that, on the 22nd June 1894, the offending article was withdrawn by an exchange of notes between Great Britain and the Congo Free State. Opinion in France was equally excited by the new agreement. It was obvious that the lease to the Congo Free State was intended to exclude France from the Nile by placing the Congo Free State as a barrier across her path. Pressure was brought to bear on King Leopold, from Paris, to renounce the rights acquired under the agreement. It is not known what communications, if any, passed between the sovereign of the Free State and the British Government, whether King Leopold asked for, or was refused, support against French pressure; but on the 14th August 1894 King Leopold signed an agreement with France by which, in exchange for France's acknowledgment of the Mbomu river as his northern frontier, His Majesty renounced all occupation and all exercise of political influence west of 30° E. longitude, and north of a line drawn from the intersection of that meridian with the parallel 5° 30' of N. latitude, and along that parallel to the Nile.

This left the way still open for France to the Nile, and in June 1896 Captain Marchand left France with secret instructions to lead an expedition into the Nile valley. On the 1st of March in the following year he left Brazzaville, and began a journey which all but plunged Great Britain and France into war. The difficulties which Captain Marchand had to overcome were mainly those connected with transport. In October 1897 the expedition reached the banks of the Sneh, the waters of which eventually flow into the Nile. Here a post was established and the *Faidherbe*, a steamer which had been carried across the Congo-Nile watershed in sections, was put together and launched. On the 1st May 1898 Marchand started on the final stage of his journey, and reached Fashoda on the 10th July, having established a chain of posts *en route*. At Fashoda the French flag was at once raised, and a "treaty" made with the local chief. Meanwhile other expeditions had been concentrating on Fashoda—a mud-flat situated in a swamp, round which for many months raged the angry passions of two great peoples. French expeditions, with a certain amount of assistance from the Emperor Menelek of Abyssinia, had been striving to reach the Nile from the east, so as to join hands with Marchand and complete the line of posts to the Abyssinian frontier. In this, however, they were unsuccessful. No better success attended the expedition under Colonel Macdonald, R.E., sent by the British Government from Uganda to anticipate the French in the occupation of the Upper Nile. It was from the north that claimants arrived to dispute with the French their right to Fashoda, and all that the occupation of that dismal post implied. In 1897 an Anglo-Egyptian army, under the direction of Sir Herbert (afterwards Lord) Kitchener, had begun to advance southwards for the reconquest of the Egyptian Sudan. On the 2nd September 1898 Khartum was captured, and the Khalifa's army dispersed. It was then that news reached the Anglo-Egyptian commander, from native sources, that there were white men flying a strange flag at Fashoda. The Sirdar at once proceeded in a steamer up the Nile, and courteously but firmly requested Captain Marchand to remove the French flag. On his refusal the Anglo-Egyptian flag was raised close to the French flag, and the dispute was referred to Europe for adjustment. Diplomatic negotiations followed between the British and French Governments. At length, on 21st

March 1899, a declaration was signed, by the terms of which France withdrew from the Nile valley and accepted a boundary line, between the British and French spheres of influence in Central Africa, which satisfied her earlier ambition by uniting the whole of her territories in North, West and Central Africa into a homogeneous whole, while effectually preventing the realization of her dream of a transcontinental empire from west to east. By this declaration it was agreed that the dividing line between the British and French spheres, north of the Congo Free State, should follow the Congo-Nile water-parting up to its intersection with the 11th parallel of north latitude, from which point it was to be "drawn as far as the 15th parallel in such a manner as to separate in principle the kingdom of Wadai from what constituted in 1882 the province of Darfur," but in no case was it to be drawn west of the 21st degree of east longitude, or east of the 23rd degree. From the 15th parallel the line took a north-westerly direction, until it intersected the Tropic of Cancer, on the southern frontier of the Turkish province of Fezzan to the south of Tripoli. French influence was to prevail west of this line, British influence to the east. Wadai was thus definitely assigned to France. This partition was and still is (1901) merely a paper partition; and it should be added that while it, of course, only binds the parties to it, the Sultan of Turkey entered a protest against the agreement as infringing his prior acquired rights both in the Sahara and in the Central Sudan.

Let us now return to the mouth of the Congo and see what was the course of events in the southern half of the continent. It will be remembered that by the agreement in which Portugal recognized the sovereignty of the Congo Free State, Portugal's claim to the southern bank of the river as far as Nokki had been admitted. Thus Portuguese possessions on the west coast extended from the Congo to the mouth of the Kunene river. In the interior the boundary with the Free State was settled as far as the Kwango river, but disputes arose as to the right to the country of Lunda, otherwise known as the territory of the Muato Yanvo. On the 25th May 1891 a treaty was signed at Lisbon, by which this large territory was divided between Portugal and the Free State, the boundary line leaving the Kwango at the 8th degree of south latitude and reaching the Kasai, one of the main southern affluents of the Congo, at the 7th degree, then passing along the *thalweg* of that river to its source in Lake Dilolo, and then along the watershed between the Zaire and the Zambezi to its intersection by the 24th meridian east of Greenwich. The interior limits of Portuguese possessions in Africa south of the equator gave rise, however, to much more serious discussions than were involved in the dispute as to the Muato Yanvo's kingdom. Portugal, as we have seen, claimed all the territories between Angola and Mozambique, and she succeeded in inducing both France and Germany, in 1886, to recognize the King of Portugal's "right to exercise his sovereign and civilizing influence in the territories which separate the Portuguese possessions of Angola and Mozambique." The publication of the treaties containing this declaration, together with a map showing Portuguese claims extending over the whole of the Zambezi valley, and over Matabeleland to the south and the greater part of Lake Nyasa to the north, immediately provoked a formal protest from the British Government. On the 13th August 1887, the British Chargé d'Affaires at Lisbon transmitted to the Portuguese minister for foreign affairs a memorandum from Lord Salisbury, in which the latter formally protested "against any claims not founded on occupa-

Portugal
in South-
West and
South-East
Africa.

tion" and contended that the doctrine of effective occupation had been admitted in principle by all the parties to the Act of Berlin. Lord Salisbury further stated that "Her Majesty's Government cannot recognize Portuguese sovereignty in territory not occupied by her in sufficient strength to enable her to maintain order, protect foreigners, and control the natives." To this Portugal replied that the doctrine of effective occupation was expressly confined by the Berlin Act to the African coast, but at the same time expeditions were hastily despatched up the Zambezi and some of its tributaries to discover traces of former Portuguese occupation. Matabeleland and the districts of Lake Nyasa were specially mentioned in the British protest as countries in which Her Majesty's Government took a special interest. As a matter of fact the extension of British influence northwards to the Zambezi had engaged the attention of the British authorities, ever since the appearance of Germany in South-West Africa and the declaration of a protectorate over Bechuanaland. There were rumours of German activity in Matabeleland, and of a Boer trek north of the Limpopo. Hunters and explorers had reported in eulogistic terms on the rich goldfields and healthy plateau lands of Matabeleland and Mashonaland, over both of which countries a powerful native chief, Lobengula, son of the great Moziligazi, claimed authority. The Matabele, or Amandebele, were a branch of the great Zulu family and a race of warriors. There were many suitors for Lobengula's favours; but on the 11th February 1888 he signed a treaty with Mr J. S. Moffat, the assistant commissioner in Bechuanaland, the effect of which was to place all his territory under British protection. Both the Portuguese and the Transvaal Boers were naturally chagrined at this extension of British influence. A number of Boers attempted unsuccessfully to trek into the country, and Portugal opposed her ancient claims to the new treaty. She contended that Lobengula's authority did not extend over Mashonaland, which she claimed as part of the Portuguese province of Sofala, and suddenly developed spasmodic activity in the distribution of flags and the establishment of stations and forts, not only in Eastern Mashonaland, but in the countries north of the Zambezi. Meanwhile preparations were being actively made for the exploitation of the mineral and other resources of Lobengula's territories. Two rival syndicates obtained, or claimed to have obtained, concessions from Lobengula; but in the summer of 1889 Mr Cecil Rhodes succeeded in amalgamating the conflicting interests, and on the 29th October of that year Her Majesty granted a charter to the British South Africa Company (see CHARTERED COMPANIES), the grantees being the Duke of Abercorn, the Duke of Fife, Lord Gifford, Mr Cecil J. Rhodes, Mr Albert Beit, Mr Albert Grey, and Mr George Cawston. The first article of the charter declared that "the principal field of the operations" of the company "shall be the region of South Africa lying immediately to the north of British Bechuanaland, and to the north and west of the South African Republic, and to the west of the Portuguese dominions." No time was lost in making preparations for effective occupation. On the advice of Mr F. C. Selous it was determined to despatch an expedition to Eastern Mashonaland by a new route, which would avoid the Matabele country. This plan was carried out in the summer of 1890, and, thanks to the rapidity with which the column moved and Mr Selous's intimate knowledge of the country, the British flag was, on 11th September, hoisted at a spot on the Makubusi river, where the town of Salisbury now stands, and the country taken possession of in the name of Queen Victoria. Disputes with the Portuguese ensued, and there were several frontier incidents which

for a time embittered the relations between the two countries.

Meanwhile, north of Zambezi, the Portuguese were making desperate but futile attempts to repair the neglect of centuries by hastily-organized expeditions and the hoisting of flags. In 1888 an attempt to close the Zambezi to British vessels was frustrated by the firmness of Lord Salisbury. In a despatch to the British minister at Lisbon, dated 25th June 1888, Lord Salisbury, after brushing aside the Portuguese claims founded on doubtful discoveries three centuries old, stated the British case in a few sentences. "It is," he wrote, "an undisputed point that the recent discoveries of the English traveller, Livingstone, were followed by organized attempts on the part of English religious and commercial bodies to open up and civilize the districts surrounding and adjoining the lake. Many British settlements have been established, the access to which from the sea is by the rivers Zambezi and Shiré. Her Majesty's Government and the British public are much interested in the welfare of these settlements. Portugal does not occupy, and has never occupied, any portion of the lake, nor of the Shiré; she has neither authority nor influence beyond the confluence of the Shiré and Zambezi, where her interior custom house, now withdrawn, was placed by the terms of the Mozambique Tariff of 1877." As a matter of historical accuracy it may be well to add that the Nyasa region has, from the first, been peculiarly associated with Scottish enterprise. Apart from the fact that Livingstone was a Scotsman, the first missions were established by the Scottish churches, the first planters were Scottish, and the "African Lakes Company," which was the pioneer in trading and transport operations, was a Scottish corporation. In 1889 it became known to the British Government that a considerable Portuguese expedition was being organized for operating in the Zambezi region. In answer to inquiries addressed to the Portuguese Government, the foreign minister stated that the object of the Serpa Pinto expedition was to visit the Portuguese settlements on the Upper Zambezi. The British Government was, even so late as 1889, averse from declaring a formal protectorate over the Nyasa region; but early in that year Mr H. H. (afterward Sir Harry) Johnston was sent out to Mozambique as British consul, with instructions to travel in the interior and report on the troubles that had arisen with the Arabs on Lake Nyasa and with the Portuguese. The discovery of a navigable mouth of the Zambezi—the Chinde—and the offer by Mr Rhodes of a subsidy of £10,000 a year from the British South Africa Company, removed some of the objections to a protectorate entertained by the British Government; but Mr Johnston's instructions were not to proclaim a protectorate unless circumstances compelled him to take that course. To his surprise, Mr Johnston learnt on his arrival at the Zambezi that Major Serpa Pinto's expedition had been suddenly deflected to the north. Hurrying forward, Mr Johnston overtook the Portuguese expedition and warned its leader that any attempt to establish political influence north of the Ruo river would compel him to take steps to protect British interests. On arrival at the Ruo, Major Serpa Pinto returned to Mozambique for instructions, and in his absence Lieutenant Coutinho crossed the river, attacked the Makalolo chiefs, and sought to obtain possession of the Shiré highlands by a *coup de main*. Mr Buchanan, the British vice-consul, lost no time in declaring the country under British protection, and his action was subsequently confirmed by Mr Johnston on his return from a treaty-making expedition on Lake Nyasa. On the news of these events reaching Europe the British Government addressed an

and
Portugal
north of
the
Zambezi.

ultimatum to Portugal, as the result of which Lieutenant Coutinho's action was disavowed, and he was ordered to withdraw the Portuguese forces south of the Ruo. But while Mr Johnston was busily engaged in concluding treaties with the native chiefs in the districts to which Portugal had no prior claim, the diplomatists in Europe were seeking for a solution of the troubles which had arisen both north and south of the Zambezi. As the result of prolonged negotiations, an agreement was signed between Great Britain and Portugal on the 20th August 1890, by which Great Britain obtained a broad belt of territory north of the Zambezi, stretching from Lake Nyasa on the east, the southern end of Tanganyika on

the north, and Lake Bangweulu on the west; while south of the Zambezi Portugal was allowed to retain the right bank of the river from a point ten miles above Zumbo, and the eastern boundary of her territory south of the river was made roughly to coincide with the 33rd degree of east longitude. The publication of the agreement aroused deep resentment in Portugal, and the Government, unable to obtain its ratification by the Chamber of Deputies, resigned. In October the abandonment of the treaty was accepted by the new Portuguese ministry as a *fait accompli*; but on the 14th November the two Governments signed an agreement for a *modus vivendi*, by which they engaged to recognize the territorial limits

SKETCH MAP ILLUSTRATING THE PARTITION OF AFRICA.

indicated in the convention of 20th August "in so far that from the date of the present agreement to the termination thereof neither Power will make treaties, accept protectorates, nor exercise any act of sovereignty within the spheres of influence assigned to the other party by the said convention." The breathing-space thus gained enabled feeling in Portugal to cool down, and on the 11th June 1891 another treaty was signed, the ratifications being exchanged on the 3rd July. This is the main treaty, defining the British and Portuguese spheres both south and north of the Zambezi.

The treaty of 1891.

It contained many other provisions relating to trade and navigation, providing *inter alia* a maximum transit duty of 3 per cent. on imports and exports crossing Portuguese territories on the east coast to the British

sphere, freedom of navigation of the Zambezi and Shiré for the ships of all nations, and stipulations as to the making of railways, roads, and telegraphs. The territorial readjustment effected left Portugal a triangular strip of territory north of the Zambezi, with its base on the Zambezi-Shiré watershed and its apex on the angle formed by the Zambezi and the Loangwa, close to Zumbo. South of the Zambezi the Portuguese frontier, after running for a short distance due south, takes an east-southeasterly direction to the Mazoe river, which it intersects at the 33rd degree of east longitude and follows that meridian to its intersection by the 18° 30' parallel of south latitude, whence it follows the eastern slope of the Manica plateau southwards to the centre of the main channel of the Sabi, follows that channel to its confluence

with the Lunte, whence it strikes directly to the north-eastern point of the frontier of the Transvaal, and follows the eastern frontier of that territory and the frontier of Swaziland to the river Maputa. The delimitation of this frontier was not accomplished without considerable difficulty and a recourse to arbitration. Some parts of the boundary north of the Zambezi were not delimited until the closing months of the 19th century. The western boundary between the British and Portuguese spheres of influence was only vaguely indicated, and had not been settled in 1900 by the Anglo-Portuguese Commission; but it was to be drawn in such a manner as to leave the Barotse country within the British sphere, Lewanika, the paramount chief of the Marotse, claiming that his territory extended much farther to the west than was admitted by the Portuguese.

Before the conclusion of the treaty of June 1891 with Portugal, the British Government had made certain arrangements for the administration of the large area north of the Zambezi reserved to British influence. On the 1st of February Mr H. H.

**British
Central
Africa.**

Johnston was appointed Imperial Commissioner in Nyasaland, and a fortnight later the British South Africa Company intimated a desire to extend its operations north of the Zambezi. Negotiations followed, and the field of operations of the Chartered Company was, on the 2nd of April 1891, extended so as to cover the whole of the British sphere of influence north of the Zambezi, with the exception of Nyasaland, the Company agreeing to appoint Mr Johnston political Administrator of its territories north of the Zambezi, now known as Northern Rhodesia, and to contribute £10,000 a year towards the cost of administration, to be applied by Mr. Johnston at his discretion either in Nyasaland or in the Company's sphere. On the 14th of May a formal protectorate was declared over Nyasaland, including the Shiré highlands and a wide belt of territory from the Anglo-German frontier on the north end of Lake Nyasa along the western shore of the lake. The name was subsequently changed to the British Central Africa Protectorate (*q.v.*). The arrangement as to the joint administration of the Protectorate and the Company's sphere lasted for some three years, and at the end of that time the Company appointed a separate administration for Northern Rhodesia, and the subsidy was withdrawn.

At the date of the assembling of the Berlin Conference the German Government had notified that the coast-line on the south-west of the continent, from the Orange river to Cape Frio, had been placed under German protection. On the 13th April 1885 the German South-West Africa Company was constituted under an order of the Imperial Cabinet with the rights of state sovereignty, including mining royalties and rights, and a railway and telegraph monopoly. In that and the following years the Germans vigorously pursued the business of treaty-making with the native chiefs in the interior; and when, in July 1890, the British and German Governments came to an agreement as to the limits of their respective spheres of influence in various parts of Africa, the boundaries of German South-West Africa were fixed in their present position. By Article III. of this important agreement the north bank of the Orange river up to the point of its intersection by the 20th degree of east longitude was made the southern boundary of the German sphere of influence. The eastern boundary followed the 20th degree of east longitude to its intersection by the 22nd parallel of south latitude, then ran eastwards along that parallel to the point of its intersection by the 21st degree of east longi-

**German
South-
West
Africa.**

tude. From that point it ran northwards along the last-named meridian to the point of its intersection by the 18th parallel of south latitude, thence eastwards along that parallel to the river Chobe, and along the main channel of that river to its junction with the Zambezi, where it terminated. The northern frontier marched with the southern boundary of Portuguese West Africa. The object of deflecting the eastern boundary near its northern termination was to give Germany access by her own territory to the upper waters of the Zambezi, and it was declared that this strip of territory was at no part to be less than twenty English miles in width.

To complete the survey of the political partition of Africa south of the Zambezi, it is necessary briefly to refer to the events connected with the South African Republic and the Orange Free State. In October 1886 the British Government made an agreement with the New Republic, a small community of Boer farmers who had set up a Government of their own, defining the frontier between the New Republic and Zululand; but less than a year later—in September 1887—the New Republic was incorporated in the South African Republic. In a convention of July–August 1890 the British Government and the Government of the South African Republic confirmed the independence of Swaziland, and on the 8th November 1893 another convention was signed with the same object; but on the 19th December 1894 the British Government agreed to the South African Republic exercising “all rights and powers of protection, legislation, jurisdiction, and administration over Swaziland and the inhabitants thereof,” subject to certain conditions and provisions, and to the non-incorporation of Swaziland in the Republic. Subsequently, on the 23rd April 1895, Tongaland was declared by proclamation to be added to the dominions of Queen Victoria, and in December 1897 Zululand and Tongaland, or Amatongaland, were incorporated with the colony of Natal. The history of the events that led up to the last Boer war cannot be recounted here (see TRANSVAAL COLONY and ORANGE RIVER COLONY), but in October 1899 the South African Republic and the Orange Free State addressed an ultimatum to Great Britain and invaded Natal and Cape Colony. As a result of the military operations that followed, the Orange Free State was, on 28th May 1900, proclaimed by Lord Roberts a British colony under the name “Orange River Colony,” and the South African Republic was on the 25th October 1900 incorporated in the British Empire as the “Transvaal Colony.”

On the east coast the two great rivals were Germany and Great Britain. Germany on the 30th December 1896, and Great Britain on the 11th June 1891, formally recognized the Rovuma river as the northern boundary of the Portuguese sphere of influence on that coast; but it was to the north of that river, over the vast area of East or East Central Africa in which the Sultan of Zanzibar claimed to exercise suzerainty, that the struggle between the two rival Powers was most acute. The independence of the Sultans of Zanzibar had been recognized by the Governments of Great Britain and France in 1862, and the Sultan's authority extended almost uninterruptedly along the coast of the mainland, from Cape Delgado in the south to Warshekh on the north—a stretch of coast more than a thousand miles long—though to the north the Sultan's authority was confined to certain ports. In Zanzibar itself, where Sir John Kirk, Livingstone's companion, was British consul-general, British influence was, when the Berlin Conference met, practically supreme, though German traders had established themselves on

Africa.**

the island and created considerable commercial interests. Away from the coasts the limits and extent of the Sultan's authority were far from being clearly defined. The Sultan himself claimed that it extended as far as Lake Tanganyika, but the claim did not rest on any very solid ground of effective occupation. The little-known region of the Great Lakes had for some time attracted the attention of the men who were directing the colonial movement in Germany; and, as we have seen, a small band of pioneers actually landed on the mainland opposite Zanzibar in November 1884, and made their first "treaty" with the chief of Mbuzini on the 19th of that month. Pushing up the Wami river the three adventurers reached the Usagara country, and concluded more "treaties," the net result being that when, in the middle of December, Dr Peters returned to the coast he brought back with him documents which were claimed to concede some 60,000 square miles of country to the German Colonization Society. Dr Peters hurried back to Berlin, and on the 17th of February 1885 the German Emperor issued a "Charter of Protection" by which His Majesty accepted the suzerainty of the newly-acquired territory, and "placed under our Imperial protection the territories in question." The conclusion of these treaties was, on the 6th March, notified to the British Government and to the Sultan of Zanzibar. Immediately on receipt of the notification the Sultan telegraphed an energetic protest to Berlin, alleging that the places placed under German protection had belonged to the Sultanate of Zanzibar from the time of his fathers. The German consul-general refused to admit the Sultan's claims, and meanwhile agents of the German society were energetically pursuing the task of treaty-making. The Sultan despatched a small force to the disputed territory, which was subsequently withdrawn, and in May sent a more imposing expedition under the command of General Mathews, the commander-in-chief of the Zanzibar army, to the Kilimanjaro district, in order to anticipate the German agents who were reported to be hastening to conclude treaties with the chiefs of Chagga and Taveta. Meanwhile Lord Granville, who was then at the Foreign Office, had taken up an extremely friendly attitude towards the German claims. Prior to these events the Sultan of Zanzibar had, on more than one occasion, practically invited Great Britain to assume a protectorate over his dominions. But the invitations had been declined. Egyptian affairs were, in the year 1885, causing considerable anxiety to the British Government, and the fact may not have been without influence on the attitude of the British foreign secretary. On the 25th May 1885, in a despatch to the British ambassador at Berlin, Lord Granville instructed Sir E. Malet to communicate the views of the British Cabinet to Prince Bismarck:—

I have to request your Excellency to state that the supposition that Her Majesty's Government have no intention of opposing the German scheme of colonization in the neighbourhood of Zanzibar is absolutely correct. Her Majesty's Government, on the contrary, view with favour these schemes, the realization of which will entail the civilization of large tracts over which hitherto no European influence has been exercised, the co-operation of Germany with Great Britain in the work of the suppression of the slave gangs, and the encouragement of the efforts of the Sultan both in the extinction of the slave trade and in the commercial development of his dominions.

In the same despatch Lord Granville instructed Sir E. Malet to intimate to the German Government that some prominent capitalists had originated a plan for a British settlement in the country between the coast and the lakes, which are the sources of the White Nile, "and for its connexion with the coast by a railway." But Her Majesty's Government would not accord to these prominent capitalists the support they had called for "unless

they were fully satisfied that every precaution was taken to ensure that it should in no way conflict with the interests of the territory that has been taken under German protectorate," and Prince Bismarck was practically invited to say whether British capitalists were or were not to receive the protection of the British Government. The reference in Lord Granville's despatch was to a proposal made by a number of British merchants and others who had long been interested in Zanzibar, and who saw in the rapid advance of Germany a menace to the interests which had hitherto been regarded as paramount in the Sultanate. In 1884 Mr H. H. Johnston had concluded treaties with the chief of Taveta, and had transferred these treaties to Mr John Hutton of Manchester. Mr Hutton, with Mr (afterwards Sir William) Mackinnon was one of the founders of what subsequently became the Imperial British East Africa Company. But in the early stages the champions of British interests in East Africa received no support from their own Government, while Germany was pushing her advantage with the energy of a recent convert to colonial expansion, and had even, on the coast, opened negotiations with the Sultan of Witu, a small territory situated north of Tana river, whose ruler claimed to be independent of Zanzibar. On the 5th May 1885 the Sultan of Witu executed a deed of sale and cession to a German subject of certain tracts of land on the coast, and later in the same year other treaties or sales of territory were effected, by which German subjects acquired rights on the coast-line claimed by the Sultan. Inland, treaties had been concluded on behalf of Germany with the chiefs of the Kilimanjaro region, and an intimation to that effect made to the British Government. But before this occurred the German Government had succeeded in extracting an acknowledgment of the validity of the earlier treaties from the Sultan of Zanzibar. Early in August a powerful German squadron appeared off Zanzibar, and on the 14th of that month the Sultan yielded to the inevitable, acknowledged the German protectorate over Usagara and Witu, and undertook to withdraw his soldiers.

Meanwhile negotiations had been opened for the appointment of an International Commission, "for the purpose of inquiring into the claims of the Sultans of Zanzibar to sovereignty over certain territories on the east coast of Africa, and of ascertaining their precise limits." The Governments to be represented were Great Britain, France, and Germany, and towards the end of 1885 commissioners were appointed. The commissioners reported on the 9th of June 1886, and assigned to the Sultan the islands of Zanzibar, Pemba, Lamu, Mafia, and a number of other small islands. On the mainland they recognized as belonging to the Sultan a continuous strip of territory, 10 sea miles in depth, from the south bank of the Minengani river, a stream a short distance south of the Rovuma, to Kipini, at the mouth of the Tana river, some 600 miles in length. North of Kipini the commissioners recognized as belonging to the Sultan the stations of Kismayu, Brava, Merurka, and Magadisho, with radii landwards of 10 sea miles, and of Warshekh with a radius of 5 sea miles. By an exchange of notes in October–November 1886 the Governments of Great Britain and Germany accepted the reports of the Delimitation Commissioners, to which the Sultan adhered on the 4th of the following December. But the British and German Governments did more than determine what territories were to be assigned to the Sultanate of Zanzibar. They agreed to a delimitation of their respective spheres of influence in East Africa. The territory to be affected by this arrangement was to be bounded on the south by the Rovuma river, "and on the north by a line which, starting from the mouth of the

*The
Sultanate
of
Zanzibar.*

Tana river, follows the course of that river or its affluents to the point of intersection of the equator and the 38th degree of east longitude, thence strikes direct to the point of intersection of the 1st degree of north latitude with the 37th degree of east longitude, where the line terminates." The line of demarcation between the British and the German spheres of influence was to start from the mouth of the river Wanga or Umba, to pass round the eastern and northern side of Lake Jipe, cross the Lumi river, pass between the territories of Taveta and Chagga, skirt the northern base of the Kilimanjaro range, and thence be drawn direct to the point on the eastern side of Victoria Nyanza which is intersected by the 1st degree of south latitude. South of this line German influence was to prevail; north of the line was the British sphere. The Sultan's dominions having been thus truncated, Germany associated herself with the recognition of the "independence" of Zanzibar in which France and Great Britain had joined in 1862. The effect of this agreement was to define the spheres of influence of the two countries as far as Victoria Nyanza, but it provided no limit to the westwards, and left the country north of the Tana river, in which Germany had already acquired some interests near the coast, open for fresh annexations. The conclusion of the agreement immediately stimulated the enterprise both of the German East Africa Association, to which Dr Peters's earlier treaties had been transferred, and of the British capitalists to whom reference had been made in Lord Granville's despatch. The German Association was incorporated by Imperial charter in March 1887, and the British capitalists formed themselves into the British East Africa Association, and on 24th May 1877 obtained, through the good offices of Sir William Mackinnon, a concession of the 10-miles strip of coast from the Umba river in the south to Kipini in the north. The Association was to have the entire administration of the territory for fifty years, and was to govern in the Sultan's name, on certain conditions as to the payment of the customs dues. The British Association further sought to extend its rights in the sphere reserved to British influence by making treaties with the native chiefs behind the coast strip, and for this purpose various expeditions were sent into the interior. When they had obtained concessions over the country for some 200 miles inland the associated capitalists applied to the British Government for a charter, which was granted on 3rd September 1888, and the Association became the Imperial British East Africa Company (see CHARTERED COMPANIES). The example set by the British company in obtaining a lease of the coast strip between the British sphere of influence and the sea was quickly followed by the German Association, which, on the 28th April 1888, concluded an agreement with the Sultan Khalifa, who had succeeded his brother Burghash, by which the Association leased the strip of Zanzibar territory between the German sphere and the sea. It was not, however, until August that the German officials took over the administration, and their want of tact and ignorance of native administration almost immediately provoked a rebellion, of so serious a character that it was not suppressed until the Imperial authorities had taken the matter in hand. Shortly after its suppression the administration was entrusted to an Imperial officer, and the Sultan's rights on the mainland strip were bought outright by Germany for four millions of marks.

Events of great importance had been happening, meanwhile, in the country to the west and north of the British sphere of influence. The British company had sent caravans into the interior to survey the country, to make treaties with the native chiefs, and to report on the commercial and agricultural possibilities.

One of these had gone up the Tana river. But another and a rival expedition was proceeding along the northern bank of this same river. Dr Carl Peters, whose energy cannot be denied, whatever may be thought of his methods, set out with an armed caravan up the Tana on the pretext of leading an expedition to the relief of Emin Pasha, who was then reported to be hemmed in by the dervishes at Wadelai. His expedition was not sanctioned by the German Government, which was at that moment receiving material assistance from Great Britain in the suppression of the Bushiri rebellion, and the British naval commander had orders to prevent his landing. But Peters succeeded in evading the British vessels and proceeded up the river, planting German flags and fighting the natives who opposed his progress. Early in 1890 he reached Kavirondo, and there found letters from Mwanga, King of Uganda, addressed to Mr F. J. Jackson, the leader of an expedition sent out by the British East Africa Company, imploring the Company's representative to come to his assistance and offering to accept the British flag. To previous letters, less plainly couched, from the King, Mr Jackson had returned the answer that his instructions were not to enter Uganda, but that he would do so in case of need. The letters that fell into Peters's hands were in reply to those from Mr Jackson. Peters did not hesitate to open the letters, and on reading them he at once proceeded to Uganda, where, with the assistance of the French Roman Catholic priests, he succeeded in inducing Mwanga to sign a loosely-worded treaty intended to place him under German protection. On hearing of this Mr Jackson at once set out for Uganda, but Peters did not wait for his arrival, leaving for the south of Victoria Nyanza some days before Jackson arrived at Mengo, Mwanga's capital. For the complicated story of European relations with Uganda, reference must be made to the article on the UGANDA PROTECTORATE. It must be sufficient to say here that, as Mwanga would not agree to Mr Jackson's proposals, Mr Jackson returned to the coast, leaving Mr Gedge at Mengo to protect the Company's interests. Captain Lugard, who had recently entered the Company's employment, was at once ordered to proceed to Uganda. But in the meantime an event of great importance had taken place, the conclusion of an agreement between Great Britain and Germany with reference to their different spheres of influence in various parts of Africa.

The Anglo-German agreement of 1st July 1890 has already been referred to in connexion with German South-West Africa. It was, however, of much greater importance in reference to East Africa. In return for the cession of Heligoland, Lord Salisbury obtained from Germany the recognition of a British protectorate over the dominions of the Sultan of Zanzibar, including the islands of Zanzibar and Pemba, but excluding the strip leased to Germany, which was subsequently ceded absolutely to Germany. Prince Bismarck further agreed to withdraw the protectorate declared over Witu and the adjoining coast up to Kismayu, in favour of Great Britain, and to recognize as within the British sphere of influence the vast area bounded, on the south by the frontier line laid down in the agreement of 1886, which was to be extended along the first parallel of south latitude across Victoria Nyanza to the frontiers of the Congo Free State; on the west by the Congo Free State and the western watershed of the Nile, and on the north by a line commencing on the coast at the north bank of the mouth of the river Juba, then ascending that bank of the river until it reached the territory reserved to the influence of Italy in Gallaland and Abyssinia,

Anglo-German agreement of 1890.

when it followed the frontier of the Italian sphere to the confines of Egypt. To the south-west of the German sphere in East Africa the boundary was formed by the eastern and northern shore of Lake Nyasa, and round the western shore to the mouth of the Songwe river, from which point it crossed the Nyasa-Tanganyika plateau to the southern end of the last-named lake, leaving the Stevenson Road on the British side of the boundary. The effect of this treaty was to remove all serious causes of dispute about territory between Germany and Great Britain in East Africa. It rendered quite valueless Dr Peters's treaty with Mwanga and his promenade along the Tana; it freed Great Britain from any fear of German competition to the northwards, and recognized that her influence extended to the western limits of the Nile valley. But, on the other hand, Great Britain had to relinquish the ambition of connecting her sphere of influence in the Nile valley with her possessions in the Nyasa-Tanganyika region. On this point Germany was quite obdurate; and, as we have already seen, an attempt subsequently made (May 1894) to secure this object by the lease of a strip of territory from the Congo Free State, was frustrated by German opposition.

Uganda having thus been assigned to the British sphere of influence by the only European Power in a position to contest its possession with her, the subsequent history of that region, and of the country between the Victoria Nyanza and the coast, must be traced in the articles on EAST AFRICA, BRITISH, and UGANDA, but it may be well briefly to record here the following facts:—The Imperial British East Africa Company, finding the burden of administration too heavy for its financial resources, and not receiving the assistance it felt itself entitled to receive from the Imperial authorities, intimated that it would be compelled to withdraw at the end of the year 1892. Funds were raised to enable the Company to continue its administration until the end of March 1893, and a strong public protest against evacuation compelled the Government to determine in favour of the retention of the country. In January 1893 Sir Gerald Portal left the coast as a special commissioner to inquire into the "best means of dealing with the country, whether through Zanzibar or otherwise." On the 31st March the Union Jack was raised, and on the 29th May a fresh treaty was concluded with King Mwanga, placing his country under British protection. A formal protectorate was declared over Uganda proper on 19th June 1894, which was subsequently extended so as to include the countries westwards towards the Congo Free State and eastwards to the British East Africa Protectorate. This latter protectorate was constituted in June 1895, when the Imperial British East Africa Company relinquished all its rights in exchange for a money payment, and the administration was assumed by the Imperial authorities.

In 1883 Italy had obtained her first formal footing on the African coast at the Bay of Assab (Aussa) on the Red Sea. In 1885 the troubles in which Egypt found herself involved compelled the Khedive and his advisers to loosen their hold on the Red Sea littoral, and, with the tacit approval of Great Britain, Italy took possession of Massawa and other ports on that coast. By 1888 Italian influence had been extended from Ras Kasar, on the north, to the northern frontier of the French colony of Obok on the south, a distance of some 650 miles. The interior limits of Italian influence were but ill defined, and King John of Abyssinia viewed with anything but a favourable eye the approach of the Italians towards the Abyssinian highlands. In January 1887 an Italian force was almost annihilated at Dogali, but the check only served to spur

on the Italian Government to fresh efforts. The Italians occupied Keren and Asmara in the interior, and eventually, in May 1889, concluded a treaty of peace and friendship with the Emperor Menelek, who had succeeded King John on the death of the latter in battle with the dervishes. This agreement, known as the Treaty of Ucialli, settled the frontiers between Abyssinia and the Italian sphere, and contained the following article:—

XVII. His Majesty the King of Kings of Ethiopia consents to avail himself of the Italian Government for any negotiations which he may enter into with the other Powers or Governments.

In Italy, and by other European Governments, this article was generally regarded as establishing an Italian protectorate over Abyssinia, but this interpretation was never accepted by the Emperor Menelek, and at no time did Italy succeed in establishing any very effective control over Abyssinian affairs. North of the Italian coast sphere the Red Sea littoral was still under Egyptian rule, while immediately to the south a small stretch of coast on the Bay of Tajura constituted the sole French possession on the East African mainland. France had, in 1862, obtained from the Danakil tribes a concession of "the harbour, roadstead, and anchorage of Obok, situated near Cape Ras Bir, with the plain extending from Ras Aly to the south, as far as Ras Dameirah to the north." It was not, however, until 1883 that the place was effectively occupied, and in the following year treaties were concluded with the Sultan and chiefs of Tajura extending the French sphere to the southern side of the gulf of that name. The East India Company had, as far back as 1840, concluded a treaty of friendship with the governor or chief of Zeila, not far from the Bay of Tajura; and when Egyptian claims to the Somali coast were withdrawn Great Britain took the opportunity to establish her influence on the northern Somali coast, opposite Aden. Between 1st May 1884 and 15th March 1886 ten treaties were concluded, placing under British influence the northern Somali coast from Ras Jibuti on the west to Bunder Ziadeh on the east. In the meantime Italy, not content with her acquisitions on the Red Sea, had been concluding treaties with the Somali chiefs on the east coast. The first treaty was made with the Sultan of Oppia on the 8th February 1889. Later in the same year the British East Africa Company transferred to Italy, the transference being subsequently approved by the Sultan of Zanzibar, the ports of Brava, Meurka, Magadisho, and Warshekh, leased from Zanzibar. On the 24th March 1891 an agreement between Italy and Great Britain fixed the northern bank of the Juba up to latitude 6° N. as the southern boundary of Italian influence in Somaliland, the boundary being provisionally prolonged along lines of latitude and longitude to the intersection of the Blue Nile with 35° E. longitude. On the 15th April 1891 a further agreement fixed the northern limit of the Italian sphere from Ras Kasar on the Red Sea to the point on the Blue Nile just mentioned. By this agreement Italy was to have the right of temporarily occupying Kassala, which was left in the Anglo-Egyptian sphere—in trust for Egypt—a right of which she availed herself in 1895. To complete the work of delimitation the British and Italian Governments, on the 5th May 1894, fixed the boundary of the British sphere of influence in Somaliland from the Anglo-French boundary, which had been settled in February 1888. The interior limit of British Somaliland thus agreed upon was subsequently modified in 1897 by an agreement with the Emperor Menelek, made by Sir Rennell Rodd on behalf of Great Britain. The effect of this agreement was to reduce the area of British Somaliland from 75,000 to 68,000 square miles.

But while Great Britain was thus lending her sanction to Italy's ambitious schemes, the Abyssinian emperor was becoming more and more incensed at Italy's pretensions to exercise a protectorate over Ethiopia. In 1883 Menelek denounced the treaty of Ucciali, and eventually, in a great battle, fought at Adowa on 1st March 1896, the Italians were disastrously defeated. By the subsequent treaty of Addis Abbaba, concluded on 26th October 1896, the whole of the country to the south of the Mareb, the Belesa, and Muna rivers was restored to Abyssinia, and Italy acknowledged the absolute independence of Abyssinia. The effect of this was practically to destroy the value of the Anglo-Italian agreement as to the boundaries to the south and west of Abyssinia; and negotiations were afterwards set on foot between the British, the Egyptian, and the Abyssinian Governments for determining the Abyssinian frontiers.

The position of Egypt is theoretically unchanged since the abolition of the Dual Control, though in fact British influence is now recognized as virtually paramount in Egypt proper. In the reconquered Anglo-Egyptian Sudan, which consists of the territory south of the 22nd parallel of latitude, the administration is carried on in accordance with the terms of a convention between the British and Egyptian Governments, signed at Cairo, 19th January 1899, under which the British and Egyptian flags are used together. Tripoli still remains a Turkish province. In Tunis the French protectorate has practically eliminated the Bey for all but ceremonial purposes. In Algeria France, in her progress south and south-west,

Egypt:
Morocco.

has come into conflict with Morocco. In the closing days of 1899 an attack by some of the inhabitants of the Tidikelt oasis on a French "scientific" mission furnished the occasion for which France had long been seeking for the occupation of a number of groups of oases in the western Sahara, known as the Tuat Oases, and consisting of Tuat, Tidikelt, and Gurara. The last two groups were occupied by French troops after some fighting, and at the end of 1900 France was preparing to make good her hold on these two groups and to establish her influence in Tuat proper, the Sultan of Morocco having protested to the European Powers against the action of France and asked for their intervention. The occupation of Igli, half-way between the frontier of Morocco proper and Tuat, by French troops further excited the Sultan's subjects. The claim of Morocco was that the tribes of the oases owed allegiance to the Sultan, and that France acknowledged them to be within the Moorish sphere of influence by the treaty of 1845, which is the only document fixing the frontier between Morocco and Algeria. At the opening of the Berlin Conference Spain had established no formal claim to any part of the coast to the south of Morocco; but while the conference was sitting, on 9th January 1885, the Spanish Government intimated that in view of the importance of the Spanish settlements on the Rio Oro, at Angra de Cintra, and at Western Bay, and of the documents signed with the independent tribes on that coast, the King of Spain had taken under his protection "the territories of the western coast of Africa comprised between the fore-mentioned Western Bay and Cape Bajador." Numerous attempts were made with France to settle the landward extension of Spain's possessions in this part of Africa, both Governments claiming to include the Adrar country within their sphere of influence; but in 1900 an agreement was come to by which Spain recognized the French claim to Adrar and agreed to the twelfth meridian west of Greenwich being the eastern boundary of the Spanish sphere, north of the Tropic of Cancer, the boundary line to the south being deflected westwards so as to leave the Sebkhah, or dry salt lake, of

Ijil to France. The same agreement settled a long-standing dispute between Spain and France as to the ownership of the district around the Muni river to the south of Cameroon, and Spain secured a block of territory, with a coast-line from the Campo river on the north to the Muni river on the south. The northern frontier is formed by the German Cameroon colony, the eastern by 11° 20' E., and the southern by the 1st parallel of north latitude to its point of intersection with the Muni river.

Apart from this small block of Spanish territory south of Cameroon, the stretch of coast between Cape Blanco and the mouth of the Congo is partitioned among four European Powers—Great Britain, France, Germany, and Portugal—and the negro republic of Liberia. Following the coast southwards from Cape Blanco we come first to the French colony of Senegal, which is indented, along the Gambia river, by the small British colony of that name, and then to the comparatively small territory of Portuguese Guinea, all that remains on this coast to represent Portugal's share in the scramble in a region where she once played so conspicuous a part. To the south of Portuguese Guinea is the French Guinea colony, and still pursuing our way south and east we come to the British colony of Sierra Leone, the republic of Liberia, the French colony of the Ivory Coast, the British Gold Coast, German Togoland, French Dahomey, the British colony of Lagos, the British territory of Southern Nigeria, the German colony of Cameroon, the Spanish settlements on the Muni river, the French Gabon colony, and the small Portuguese *enclave* north of the Congo, of which the principal town is Kabinda, which is administratively part of the Angola colony. When the General Act of the Berlin Conference was signed the whole of this coast-line had not been formally claimed; but no time was lost by the Powers interested in notifying claims to the unappropriated sections, and the conflicting claims put forward necessitated frequent adjustments by international agreements. Before describing the results of these agreements, both on the coast and in the interior, it may be interesting to glance briefly at one or two of the main features of the problem which so many rival Powers were approaching from their several standpoints. The dominant part in West Africa has been played by France. Her anxiety to connect her West African possessions with Southern Algeria, and her Congo colony with both, has already been alluded to. Ancillary to this desire was the wish to establish a continuous territorial connexion between her scattered possessions on the West African coast. When this design was consciously adopted as the object of French statesmanship, it is very difficult to say; but for several years before the Berlin Conference military and exploring expeditions had been pushed forward into the great Niger bend from the upper waters of the Senegal, and the purpose became clearer and more defined in the strenuous years of struggle that followed the Conference. The exhaustion of Portugal, the apathy of the British Government, and the late arrival of Germany in the field, are all elements that favoured the success of France's West African policy. If, in her larger design of joining on her empire in the Western Sudan to her possessions on the Congo, she experienced a check by reason of the vigour with which British interests were pushed on the Middle Niger and eastwards to Lake Chad, the credit for this cannot be claimed by the British Government, but is due entirely to the Royal-Niger Company and its distinguished governor, Sir George Taubman Goldie. France's double object was to secure as large a share of the Niger basin as possible, and to make Lake Chad a French lake. In this latter object she was not wholly successful, and

*Division
of West
Africa.*

for the much-desired communication between the Western Sudan and the Congo was reluctantly compelled to go round the northern and eastern shores of the lake, instead of through the richer and more populous regions to the west and south of the lake. The real struggle in West Africa was between France and Great Britain; but before tracing the steps of that historic contest, it may be well to deal briefly with the part played by the other Powers in West Africa.

Portuguese Guinea, with a coast-line of some 200 miles, is entirely surrounded by French possessions. Its frontiers were fixed by an agreement signed at Paris on the 12th May 1886. The northern frontier extends almost due east from Cape Roxo for about 200 miles, then the boundary turns due south for 80 or 90 miles, and then sweeps west and south in a curve to the mouth of the river Cajet. By another article in the same agreement the boundaries of the Portuguese Congo *enclave* with the French Congo colony are determined.

The negro republic of Liberia has a coast-line of about 350 miles in length, stretching from the river Mano and the frontier of Sierra Leone to the river Cavally and the French Ivory Coast. Its interior limits were fixed by agreements with Great Britain on the 11th November 1885, and with France on the 8th December 1892. Starting from the left bank of the Mano river, the frontier extends generally in a north-easterly and northern direction, the coast-line having been traced by an Anglo-Liberian Boundary Commission, until it reaches a point about half-way between the 8th and 9th parallels of north latitude, when it strikes due east to beyond the 9th meridian of west longitude, then strikes south-east, and after a short run due east intersects the Cavally river, which it follows to the coast.

It will be remembered that Dr Nachtigal, while the proposals for the Berlin Conference were under discussion, had planted the German flag on the coast of Togo and in Cameroon in the month of July 1884. In Cameroon Germany found herself with Great Britain for a neighbour to the north, and with France as her southern neighbour on the Gabun river. The utmost activity was displayed in making treaties with native chiefs, and in securing as wide a range of coast for German enterprise as was possible. In May 1885 a provisional agreement was made between Great Britain and Germany as to the northern limits of Germany's activity. This was subsequently modified in August 1886, and on the 28th March 1887 Great Britain renounced in favour of Germany her sovereignty over Ambas Bay. In the famous agreement of 1st July 1890 a "provisional line of demarcation" was adopted, starting from the head of the Rio del Rey creek and going to the point, about 9° 8' E. longitude, marked "rapids" on the British Admiralty Chart. By a further agreement of 14th April 1893, the right bank of the Rio del Rey was made the boundary between the Oil Rivers Protectorate (now Southern Nigeria) and Cameroon. In the following November (1893) the boundary was continued from the "rapids" before mentioned, on the Old Calabar or Cross river, in a straight line towards the centre of the town of Yola, on the Benué river. Yola itself, with a radius of some 3 miles, was left in the British sphere, and the German boundary followed the circle eastwards from the point of intersection as it neared Yola until it met the Benué river. From that point it crossed the river to the intersection of the 13th degree of longitude with the 10th degree of north latitude, and then made direct for a point on the southern shore of Lake Chad "situated 35 minutes east of the meridian of

Kuka, this being the distance between the meridian of Kuka and the 14th meridian east of Greenwich, measured on the map (by Kiepert) published in the German *Kolonial Atlas* of 1892." Provision was made for settling a new terminal point of the German boundary on Lake Chad, should our present want of knowledge of the geography of that region render such an alteration desirable. By this agreement the British Government withdrew from a considerable section of the upper waters of the Benué with which the Royal Niger Company had entered into relations. The object of making this sacrifice was, however, apparent. France was, as we have seen, eagerly desirous of securing the whole of Lake Chad for herself. By giving Germany access to the lake Great Britain at the same time satisfied German ambition as to the hinterland of the Cameroon colony and interposed a barrier against the junction of the French Congo and the French Sudan to the south and west of the lake. The limit of Germany's possible extension eastwards was fixed at the basin of the river Shari, and Darfur, Kordofan, and the Bahr-el-Ghazal were to be excluded from her sphere of influence. Germany now found herself in a position to come to terms with France as to the southern and eastern limits of Cameroon. She had already, on the 24th December 1885, signed a protocol with France fixing her southern frontier from the mouth of the river Campo to the intersection of that river with the 10th degree of east longitude, thence along the parallel of latitude to the point of its intersection with 15° E. longitude. But to the east German explorers were crossing the track of French explorers from the northern bank of the Mobangi, and the need for an agreement was obvious. Accordingly, on the 4th February 1894, a protocol—which, some weeks later, was confirmed by a convention—was signed at Berlin, by which France accepted the presence of Germany on Lake Chad as a *fait accompli* and effected the best bargain she could by making the left bank of the Shari river, from its outlet into Lake Chad to the 10th parallel of north latitude, the eastern limit of German extension. From this point the boundary line went due west some 230 miles, then turned south, and with various indentations joined the south-eastern frontier, which had been slightly extended so as to give Germany access to the Sangha river—a tributary of the Congo. Thus, early in 1894, the German Cameroon colony had reached its present definite limits.

The German Togoland Settlements occupy a narrow strip of the Guinea Coast, some 35 miles only in length, wedged in between the British Gold Coast and French Dahomey. At first France was inclined to dispute Germany's claims to Little Popo and Porto Seguro; but in December 1885 the French Government acknowledged the German protectorate over these places, and the boundary between French and German territory, which runs in an irregular line almost due north from the coast to the 11th degree of latitude, was laid down by the Franco-German Convention of 12th July 1897. It was not, however, until the end of 1899, after two years of arduous and constantly-interrupted labours, that the Joint Commission completed the work of delimitation. The fixing of the 11th parallel as the northern boundary of German expansion towards the interior was not accomplished without some sacrifice of German ambitions. Having secured an opening on Lake Chad for her Cameroon colony, Germany was anxious to obtain a footing on the Middle Niger for Togoland. German expeditions reached Gando, one of the tributary states of the Sokoto empire on the Middle Niger, and, notwithstanding the existence of prior treaties with Great Britain, sought to conclude agreements with the Sultan of

that country. But this German ambition conflicted both with the British and the French designs in West Africa, and eventually Germany had to be content with the 11th parallel as her northern frontier. On the west the Togoland frontier on the coast was fixed in July 1886 by British and German commissioners at 1° 10' E. longitude, and its extension towards the interior laid down for a short distance. By a further agreement in 1888 the boundary was extended so as to leave the district of Towe, Kowe, and Agotime within the German sphere, and to include the countries of Aquamoo and Crépee within the British protectorate. A neutral zone farther north was also agreed upon at the same time. The agreement of 1st July 1890, already so frequently referred to, defined the limits up to this neutral zone; but it was not until November 1899 that, as part of the Samoa Settlement, this neutral zone was partitioned between the two Powers in such a manner as to leave the important trading centre of Salaga to Great Britain and that of Yendi to Germany. At the same time the territory to the north of the neutral zone up to the 11th parallel was divided between the Gold Coast and Togoland, and the present limits of both colonies were then definitely determined.

The story of the struggle between France and Great Britain in West Africa may roughly be divided into two sections, the first dealing with the Coast colonies, the second dealing with the struggle for the Middle Niger and Lake Chad. As regards the coast colonies, France was wholly successful in her design of isolating all Great

Anglo-French Competition in West Africa.

Britain's separate possessions in that region, and of securing for herself undisputed possession of the Upper Niger and of the countries lying within the great bend of that river. When too late, the British Government awoke to the consciousness of what was at stake; but France had obtained too great a start. French governors of the Senegal had succeeded, before the Berlin Conference, in establishing forts on the Upper Niger, and the advantage thus gained was steadily pursued. Every winter season French posts were pushed farther and farther along the river, or in the vast regions watered by the southern tributaries of the Senegal and Niger rivers. The two most formidable chiefs encountered by France were Ahmadu, a son of the famous El-Haj-Omar, and Samory, a man of humble origin who had risen by force of character to be the ruler of an immense area of country in the Upper Niger basin. Campaign after campaign was fought against this formidable chief by Gallieni, Desbordes, Frey, Archinard, and other French officers; but it was not until September 1898 that Samory's power was finally broken, and he himself captured. In 1887 the Almamy of Futa Jallon, who had formerly been anxious to obtain British protection, signed a treaty placing the whole of that mountainous region under French protection. Simultaneously with her military operations France undertook a series of splendid exploring expeditions in the Niger countries. In 1888-90 Captain Binger traversed the regions between the Upper Niger and the Guinea Coast, making treaties all along his route. In the campaign of 1890-91 Segou, one of Ahmadu's principal towns, was captured by Colonel Archinard. In 1891-92 Captain Monteil traversed the Niger bend from west to east, and from Say made his way to Lake Chad, returning to Europe across the Sahara to the Mediterranean. In December 1893 Timbuktu was occupied by Colonel Bonnier, in defiance of the order of the civil authorities, and every year saw one or more fresh expeditions launched by France, regardless of cost, into the Niger basin. This ceaseless activity met with its reward. Great Britain found herself compelled to acknowledge accomplished facts and to conclude agree-

ments with France, which left her colonies mere coast patches, with a very limited extension towards the interior. On the 10th August 1889 an agreement was signed by which the Gambia colony and protectorate was confined to a narrow strip of territory on both banks of the river for about 200 miles from the sea. In June 1882 and in August 1889 provisional agreements were made with France fixing the western and northern limits of Sierra Leone, and commissioners were appointed to trace the line of demarcation agreed upon by the two Governments. But the commissioners failed to agree, and on the 21st January 1895 a fresh agreement was made, the boundary being subsequently traced by a mixed commission. Sierra Leone, as now definitely constituted, has a coast-line of about 180 miles and a maximum extension towards the interior of some 200 miles.

At the date of the Berlin Conference the present colonies of Lagos and the Gold Coast constituted a single colony under the title of the Gold Coast Colony, but on the 13th January 1886 the Gold Coast Settlements were erected into a separate colony. The coast limits of the new colony were declared to extend from 5° W. longitude to 2° E. longitude, but these limits were subsequently curtailed by agreements with France and Germany. We have already followed the course of the arrangements that fixed the eastern frontier of the Gold Coast Colony and its hinterland in connexion with German Togoland. On the western frontier it marches with the French colony of the Ivory Coast, and in August 1889 the two Governments agreed that the frontier should start from the neighbourhood of the Tanoe lagoon, and river of the same name, and should be prolonged to the 9th degree of north latitude in accordance with the treaties concluded by the two Governments with the natives, Great Britain being allowed full liberty of action as regards the Ashantis. Commissioners having failed to agree as to the delimitation of the frontier, plenipotentiaries were appointed in Europe by the two Governments, and on the 12th July 1893 an agreement was signed setting out in detail the course of the frontier up to the 9th degree of north latitude. In August 1896, following the destruction of the Ashanti power and the deportation of King Prempeh, as a result of the second Ashanti campaign, a British protectorate was declared over the whole of the Ashanti territories and a Resident was installed at Kumassi. But no northern limit had been fixed by the 1893 agreement beyond the 9th parallel, and the countries to the north—Gurunsi (Grusi), Mossi, and Gurma—were entered from all sides by rival British, French, and German expeditions. The conflicting claims established by these rival expeditions may, however, best be considered in connexion with the struggle for supremacy on the Middle Niger, and in the Chad region, to which we must now turn.

A few days before the meeting of the Berlin Conference Sir George Goldie had succeeded in buying up all the French interests on the Lower Niger. The British company's influence had at that date *The Middle Niger and Lake Chad.* been extended by treaties with the native chiefs up the main Niger stream to its junction with the Benué, and some distance along this latter river. But the great Fulah States of the Central Sudan were still outside European influence, and this fact did not escape attention in Germany. German merchants had been settled for some years on the coast, and one of them, Herr Flegel, had displayed great interest in, and activity on, the river. He recognized that in the densely-populated States of the Middle Niger, Sokoto and Gando, and in Bornu to the west of Lake Chad, there was a magnificent field for Germany's new-born colonizing zeal. The German African Society and the German Colonial Society listened

eagerly to Herr Flegel's proposals, and in April 1885 he left Berlin on a mission to the Fulah states of Sokoto and Gando. But it was impossible to keep his intentions entirely secret, and the British National African Association had no desire to see the French rivals, whom they had with so much difficulty dislodged from the river, replaced by the even more troublesome German. Accordingly Mr Joseph Thomson, the young Scottish explorer, was sent out to the Niger, and had the satisfaction of concluding on the 1st June 1885 a treaty with "Umoru, King of the Mussulmans of the Sudan and Sultan of Sokoto," which practically secured the whole of the trading rights and the control of the Sultan's foreign relations to the British company. Mr Thomson concluded a similar treaty with the Sultan of Gando, so as to provide against the possibility of its being alleged that Gando was an independent state and not subject to the suzerainty of the Sultan of Sokoto. As Mr Thomson descended the river with his treaties, he met Herr Flegel going up the river, with bundles of German flags and presents for the chiefs. The German Government recognized that they had been forestalled, and, except for the despairing attempt many years later to establish relations with Gando from Togoland, Germany dropped out of the competition for the Western Sudan and left the field to France and Great Britain. After this first great success the National African Company renewed its efforts to obtain a charter from the British Government, and on the 10th July 1886 the charter was granted, and the company became "The Royal Niger Company, chartered and limited." In June of the previous year a British protectorate had been proclaimed over the whole of the coast from the Rio del Rey to the Lagos frontier, and on the 13th January 1886 the Lagos Settlements had been separated from the Gold Coast and erected into a separate colony. It may be convenient to state here that the eastern boundary of Lagos with French territory was determined in the Anglo-French agreement of 10th August 1889, which provided that "the line of demarcation between the spheres of influence of the two powers shall be identical with the meridian which intersects the territory of Porto Novo at the Ajarra creek, leaving Pokrah, or Pokéa, to the English colony of Lagos. It shall follow the above-mentioned meridian as far as the 9th degree of north latitude, where it shall stop." Thus both in the Gold Coast hinterland and in the Lagos hinterland a door was left wide open to the north of the 9th parallel.

Notwithstanding her strenuous efforts, France, in her advance down the Niger from Senegal, did not succeed in reaching Sego until the winter of 1890-91, and the rapid advance of British influence up the river raised serious fears lest the Royal Niger Company should reach Timbuktu before France could forestall her. It was, no doubt, this consideration that induced the French Government to consent to the insertion in the agreement of 5th August 1890, by which Great Britain recognized France's protectorate over Madagascar, of the following article:—

The Government of Her Britannic Majesty recognizes the sphere of influence of France to the south of her Mediterranean possessions up to a line from Say on the Niger to Barraua on Lake Chad, drawn in such a manner as to comprise in the sphere of action of the Niger Company all that fairly belongs to the kingdom of Sokoto; the line to be determined by the commissioners to be appointed.

The commissioners never were in fact appointed, and the proper meaning to be attached to this article subsequently became a subject of bitter controversy between the two countries. An examination of the map of West Africa will show what possibilities of trouble were left open at the end of 1890 by the various agreements concluded up to that date. From Say on the Niger to the northern limit of the Lagos frontier there was no bound-

ary line between the French and British spheres of influence. To the north of the Gold Coast and of the French Ivory Coast Colony the way was equally open to Great Britain and to France, while the vagueness of the Say-Barruwa line left an opening of which France was quick to avail herself. Captain Monteil started on his journey in 1890, immediately after the conclusion of the August agreement; but he did not hesitate to pass well to the south of the Say-Barruwa line, and to attempt to conclude treaties with chiefs who were, beyond all question, within the British sphere. Still farther south, on the Benué river, the two expeditions of Lieutenant Mizon—in 1890 and in 1892—failed to do any real harm to British interests.

In 1892 an event happened which had an important bearing on the future course of the dispute. After a troublesome war with Behanzin, king of the important native state of Dahomey, France annexed some portion of Dahomeyan territory on the coast, and declared a protectorate over the rest of the kingdom. In 1894 Dahomey was divided into two kingdoms, and the new sovereigns were appointed by France and accepted the French protectorate. Thus was removed the barrier which had up to that time prevented France from pushing her way Nigerwards from her possessions on the Slave Coast, as well as from the Upper Niger and the Ivory Coast. Meanwhile her progress from both these directions had been considerable, and in particular Timbuktu had been occupied in the last days of 1893.

In 1894 it appears to have been suddenly realized in France that, for the development of the vast regions which she was placing under her protection in West Africa, it was extremely desirable that she should obtain free access to the navigable portions of the Niger. In the neighbourhood of Bussa there is a long stretch of the river so impeded by rapids that navigation is practically impossible, except in small boats and at considerable risk. Below these rapids France had no foothold on the river, both banks from Bussa to the sea being within the British sphere. In 1890 the Royal Niger Company had concluded a treaty with the Emir and chiefs of Bussa (or Borgu); but the French declared that the real paramount chief of Borgu was not the king of Bussa, but the king of Nikki, and three expeditions were despatched in hot haste to Nikki to take the king under French protection. Sir George Goldie, however, was not to be baffled. While maintaining the validity of the earlier treaty with Bussa, he despatched Captain (now General) Lugard to Nikki, and Captain Lugard was successful in distancing all his French competitors by several days, reaching Nikki on the 5th November 1894, and concluding a treaty with the king and chiefs. The French expeditions, which were in great strength, did not hesitate on their arrival to compel the king to execute fresh treaties with France, and with these in their possession they returned to Dahomey. Shortly afterwards a fresh act of aggression was committed. On 13th February 1895 a French officer, Commandant Toutée, arrived on the right bank of the Niger opposite Bajibo and built a fort. His presence there was notified to the Royal Niger Company, who protested to the British Government against this invasion of their territory. Lord Rosebery, who was then foreign minister, at once made inquiries in Paris, and received the assurance that Commandant Toutée was "a private traveller." Eventually Commandant Toutée was ordered to withdraw, and the fort was occupied by the Royal Niger Company's troops. Commandant Toutée subsequently published the official instructions from the French Government under which he had acted. It was thought that the recognition of the British claims, involved in the withdrawal of Commandant Toutée, had marked the final abandonment by France of the attempt

to establish herself on the navigable portions of the Niger below Bussa, but in 1897 the attempt was renewed in the most determined manner. In February of that year a French force suddenly occupied Bussa, and this act was quickly followed by the occupation of Gomba and Ilo higher up the river. In November 1897 Nikki was occupied. The situation on the Niger had so obviously been outgrowing the capacity of a chartered company that for some time before these occurrences the assumption of responsibility for the whole of the Niger region by the Imperial authorities had been practically decided on; and early in 1898 Colonel Lugard was sent out to the Niger with a number of Imperial officers to raise a local force in preparation for the contemplated change. The advance of the French forces from the south and west was the signal for an advance of British troops from the Niger, from Lagos, and from the Gold Coast protectorate. The situation thus created was extremely serious. The British and French flags were flying in close proximity, in some cases in the same village. Meanwhile the diplomats were busy in London and in Paris, and in the latter capital a commission sat for many months to adjust the conflicting claims. Fortunately, by the tact and forbearance of the officers on both sides, no local incident occurred to precipitate a collision, and on the 14th June 1898 a convention was signed by Sir Edward Monson and M. Hanotaux, which finally removed all causes of dispute as to the spheres of influence of the two countries in West Africa; and, subject to the division of the small area in the hinterland of the Gold Coast and Togoland between Great Britain and Germany, which was effected in November 1899, completed the partition of this part of the continent.

The settlement effected was in the nature of a compromise. France withdrew from Bussa, Gomba, and Ilo, the frontier line west of the Niger being drawn from the 9th parallel to a point 10 miles, as the crow flies, above Giri, the port of Ilo. France was thus shut out from the navigable portion of the Middle and Lower Niger; but for purely commercial purposes Great Britain agreed to lease to France two small plots of land on the river—the one on the right bank between Leaba and the mouth of the Moshi river, the other at one of the mouths of the Niger. By accepting this line Great Britain abandoned Nikki and a great part of Borgu, as well as some part of Gando to France. East of the Niger the Say-Barruwa line was modified in favour of France. From the point indicated 10 miles above Giri the boundary follows the Niger as far as the mouth of a dry water-course called the Dallul Mauri, which it follows till it cuts the circumference of a circle drawn from the centre of the town of Sokoto with a radius of a hundred miles. The line then follows the northern arc of this circle till its point of intersection with the 14th parallel of north latitude, which it follows eastwards for a distance of 70 miles, then dips due south until it reaches the parallel of 13° 20' north latitude, then runs eastwards along this parallel for a distance of 250 miles, then turns due north until it regains the 14th parallel, then runs eastwards again along that parallel as far as its intersection with the meridian, passing 35' east of the centre of the town of Kuka, and thence follows this meridian southwards until its intersection with the southern shore of Lake Chad, at which point, it will be remembered, the Anglo-German frontier reaches its northern limit. This line assigns to France parts of both Sokoto and Bornu. In the Gold Coast hinterland the French withdrew from Wa, and Great Britain abandoned all claim to Mossi, though the capital of the latter country, together with a further extensive area in the territory assigned to both countries, is declared to be equally free, so far as

The Anglo-French agreement of June 1898.

trade and navigation are concerned, to the subjects and protected persons of both nationalities. The western boundary of the Gold Coast was prolonged along the Black Volta as far as latitude 11° north, and this parallel was followed with slight deflections to the Togoland frontier. In consequence of the acute crisis which shortly afterwards occurred between France and Great Britain on the Upper Nile, the ratification of this agreement was delayed until after the conclusion of the Fashoda agreement of March 1899 already referred to. In 1900 the two patches on the Niger leased to France were selected by commissioners representing the two countries, and in the same year the Anglo-French frontier from Lagos to the west bank of the Niger was delimited. But east of the Niger to Lake Chad it had not been found possible even to make a survey of the country through which the boundary will run, before the close of the 19th century.

The settlement of the matters in dispute with France enabled the British Government to carry out several changes in the administration of British Nigeria, which had been in contemplation for some time. On the 1st January 1900 the Imperial authorities took over the whole of the territories of the Royal Niger Company, which, with reduced capital, became henceforth a purely commercial undertaking. The Lagos protectorate was extended to the northwards, the Niger Coast Protectorate became Southern Nigeria with extended frontiers, and the greater part of the territories formerly administered by the company were constituted into Northern Nigeria—all three administrations being placed under the Colonial Office. In like manner France, having definitely fixed her international frontiers, turned her attention to a rearrangement of her possessions. The French Sudan was abolished as an administrative entity, large slices of territory were added on to Dahomey, the Ivory Coast Colony, French Guinea, and Senegal, the portions not assigned to these colonies, all of which were placed under civil administration, being created military districts. For the limits assigned to the various French colonies in West Africa, reference must be made to the articles dealing with each.

There are, around the coast, numerous islands or groups of islands, which are regarded by geographers as outliers of the African mainland. The majority of these African islands were occupied by one or other of the European Powers long before the period of continental partition. The Madeira Islands to the west of Morocco; the Bissagos Islands, off the Guinea Coast; and Prince's Island and St Thomas' Island, in the Gulf of Guinea, are Portuguese possessions of old standing; while in the Canary Islands and Fernando Po Spain possesses remnants of her ancient colonial empire which are a more valuable asset than any she has acquired in recent times on the mainland. St Helena in the Atlantic, Mauritius, and some small groups north of Madagascar in the Indian Ocean, are British possessions acquired long prior to the opening of the last quarter of the 19th century. Zanzibar, Pemba, and some smaller islands which the Sultan was allowed to retain were, as has already been stated, placed under British protection in 1890, and the island of Socotra was placed under the "gracious favour and protection" of Great Britain on 23rd April 1886. France's ownership of Réunion dates back to the 17th century, but the Comoro Archipelago was not placed under French protection until April 1886. None of these islands, with the exception of the Zanzibar group, have, however, materially affected the partition of the continent, and they need not be enumerated in the table which follows. But the important island of Madagascar stands in a different category, both on account of its size and because it was

African Islands.

during the period under review that it passed through the various stages which led up to its becoming a French colony. The first step was the placing of the foreign relations of the island under French control, which was effected by the treaty of 17th December 1885, following the Franco-Malagasy war that had broken out in 1883. In 1890 Great Britain and Germany recognized a French protectorate over the island, but the Hova government declined to acquiesce in this view, and in May 1895 France sent an expedition to enforce her claims. The capital was occupied on 1st October in the same year, when Queen Ranavalona signed a convention recognizing the French protectorate. In January 1896 the island was declared a French possession, and on 6th August was declared to be a French colony. In February 1897 the last vestige of ancient rule was swept away by the deportation of the queen.

Although the "Brussels Act" of 1890 did not affect the actual territorial partition of Africa, it had a direct bearing on the manner in which the Powers discharged the obligations which they assumed in acquiring African territory, and must therefore be briefly referred to here. The British Government had for long borne the greater part of the burden of combating the slave trade on the east coast of Africa and in the Indian Ocean, but the changed conditions which resulted from the appearance of other European Powers in Africa induced Lord Salisbury, then foreign secretary, to address, in the autumn of 1888, an invitation to the King of the Belgians to take the initiative in inviting a conference of the Powers at Brussels to concert measures for "the gradual suppression of the slave trade on the continent of Africa, and the immediate closing of all the external markets which it still supplies." The conference assembled in November 1889, and on the 2nd July 1890 a "General Act" was signed subject to the ratification of the various Governments represented, ratification taking place subsequently at different dates, and in the case of France with certain reservations. The General Act began with a declaration of the means which the Powers were of opinion might be most effectually adopted for "putting an end to the crimes and devastations engendered by the traffic in African slaves, protecting effectively the aboriginal populations of Africa, and ensuring for that vast continent the benefits of peace and civilization." It proceeded to lay down certain rules and regulations of a practical character on the lines suggested. The Act covers a wide field, and includes no less than a hundred separate articles. It established a zone "between the 20th parallel of north latitude and the 22nd parallel of south latitude, and extending westward to the Atlantic Ocean and eastward to the Indian Ocean and its dependencies, comprising the islands adjacent to the coast as far as 100 nautical miles from the shore," within which the importation of firearms and ammunition was forbidden except in certain specified cases, and within which also the Powers undertook either to prohibit altogether the importation and manufacture of spirituous liquors, or to impose duties not below an agreed-on minimum. An elaborate series of rules were framed for the prevention of the transit of slaves by sea, the conditions on which European Powers were to grant to natives the right to fly the flag of the protecting power, and regulating the procedure connected with the right of search on vessels flying a foreign flag. The Brussels Act was in effect a joint declaration by the signatory Powers of their joint and several responsibility towards the African native, and notwithstanding the fact that many of its articles have proved difficult, if not impossible, of enforcement, the solemn engagement taken by Europe in the face of the world has undoubtedly exercised a material influence on the action of several of the Powers.

Thus by the close of the 19th century the political partition of Africa had practically been completed. There remained still for settlement various questions of frontier, as between Great Britain, Egypt, and Abyssinia in North-East Africa, and between France and Morocco in the north-western corner of the continent. The limits of Barotseland to the west had to be determined by Great Britain and Portugal, and much delimitation work had still to be done. But in its broad outlines the partition of Africa was begun and ended in the short space of a quarter of a century. Much labour is necessary before the actual area of the continent and its subdivisions can be accurately determined, but in the following table the figures are at least approximately correct, and may be taken to represent the political situation in Africa, from the European standpoint, at the opening of the 20th century. It is perhaps well to add that in fact large areas of the spheres assigned to different European Powers are still under native rulers who have in no way admitted the title of their European overlords.

Africa, Central. See CENTRAL AFRICA.

Africa, East. See EAST AFRICA.

Aga Khan I., HIS HIGHNESS THE (1800-1881), was the title accorded by general consent to HASAN ALI SHAH (born in Persia, 1800), when, in early life, he first settled in Bombay under the protection of the British Government. He was believed to have descended in direct line from Ali by his wife Fatima, the daughter of the Prophet Mahommed. Ali's son, Hoosein, having married a daughter of one of the rulers of Persia before the time of Mahommed, the Aga Khan traced his descent from the royal house of Persia from the most remote, almost prehistoric, times. His ancestors had also ruled in Egypt as Khalifs of the Beni-Fatamites for a number of years at a period coeval with the Crusades. Before the Aga Khan emigrated from Persia he was appointed by the Emperor Fateh Ali Shah to be governor-general of the extensive and important province of Kerman. His rule was noted for firmness, moderation, and high political sagacity, and he succeeded for a long time in retaining the friendship and confidence of his master the Shah, although his career was beset with political intrigues and jealousy on the part of rival and court favourites and with internal turbulence. At last, however, the fate usual to statesmen in oriental countries overtook him, and he incurred the mortal displeasure of Fateh Ali Shah. He fled from Persia and sought protection in British territory, preferring to settle down eventually in India, making Bombay his headquarters. At that period the first Afghan War was at its height, and in crossing over from Persia through Afghanistan the Aga Khan found opportunities of rendering valuable services to the British army, and thus cast in his lot for ever with the British. A few years later he rendered similar conspicuous services in the course of the Scinde campaign, when his help was utilized by Napier in the process of subduing the frontier tribes, a large number of whom acknowledged the Aga's authority as their spiritual head. Napier held his Moslem ally in great esteem, and entertained a very

high opinion of his political acumen and chivalry as a leader and soldier. The Aga Khan reciprocated the distinguished British commander's confidence and friendship by giving repeated proofs of his devotion and attachment to the British Government, and when he finally settled down in India, his position as the leader of the large Ismailiah section of Mahommedan British subjects was recognized by the Government, and the title of His Highness was conferred on him, with a large pension. From that time until his death in 1881, the Aga Khan, while leading the life of a peaceful and peacemaking citizen, under the protection of British rule, continued to discharge his sacerdotal functions, not only among his followers in India, but towards the more numerous communities which acknowledged his religious sway in distant countries such as Afghanistan, Khorassan, Persia, Arabia, Central Asia, and even distant Syria and Morocco. He remained throughout unflinchingly loyal to the British *Raj*, and by his vast and unquestioned influence among the frontier tribes on the northern borders of India he exercised a control over their unruly and wild passions in times of trouble, which proved of invaluable service in the several expeditions led by British arms on the north-west frontier of India. He was also the means of checking the fanaticism of the more turbulent Mahommedans in British India, which in times of internal troubles and misunderstandings finds vent in the shape of religious or political riots.

He was succeeded by his eldest son, AGA KHAN II. This prince continued the traditions and work of his father in a manner that won the approbation of the local Government, and earned for him the distinction of a knighthood of the order of the Indian Empire, and a seat in the Legislative Council of Bombay.

AGA KHAN III. (Sultan Mahommed Shah), only son of the foregoing, succeeded him on his death in 1885, and is the present head of the family and its devotees. He was born in 1877, and, under the fostering care of his mother, a daughter of the ruling house of Persia, has been given not only that religious and oriental education which his position as the religious leader of the Ismailiahs made indispensable, but a sound European training, a boon denied to his father

and grandfather. This blending of the two systems of education has produced the happy result of fitting this Moslem chief in an eminent degree both for the sacerdotal functions which appertain to his spiritual position, and for those social duties of a great and enlightened leader which he is called upon to discharge by virtue of that position. He has travelled in distant parts of the world to receive the homage of his followers, and with the object either of settling differences or of advancing their welfare by pecuniary help and personal advice and guidance. The distinction of a Knight Commander of the Indian Empire was conferred upon him by Queen Victoria in 1897, and he has received like recognition for his public services from the German Emperor, the Sultan of Turkey, the Shah of Persia, and other potentates.

(M. M. B.)

Agades. See SAHARA.

Agassiz, Alexander (Emanuel) (1835—), American scientist, son of Louis Agassiz, was born in Neuchâtel, Switzerland, 17th December 1835. He came to the United States with his father in 1846; graduated at Harvard in 1855, subsequently studying engineering and chemistry, and taking the degree of bachelor of science at the Lawrence Scientific School of the same institution in 1857; taught for a time in his father's school for girls in Cambridge; and in 1859 entered upon his scientific career by becoming an assistant in the United States Coast Survey. Thenceforward he became a specialist in marine ichthyology, but devoted much time to the investigation, superintendence, and exploitation of mines, being superintendent of the Calumet and Hecla copper mines, Lake Superior (the richest in the world) from 1866 to 1869, and afterwards, as a stockholder, acquiring a fortune, out of which he gave to Harvard, for the Museum of Comparative Zoology and other purposes, some \$500,000. In 1875 he surveyed Lake Titicaca, Peru; examined the copper mines of Peru and Chile; and made a collection of Peruvian antiquities for the museum, in which he had been an assistant, under his father, from time to time, and of which he was curator 1874-85, when he resigned. He assisted Sir Wyville Thomson in the examination and classification of the collections of the *Challenger* exploring expedition, and wrote the *Review of the Echini* (2 vols., 1872-74) in the reports. Between 1877 and 1880 he took part in the three dredging expeditions of the steamer *Blake*, of the United States Coast Survey, and presented a full account of them in two volumes (1888). Of his other writings on marine zoology most are contained in the bulletins and memoirs of the Museum of Comparative Zoology; but he published in 1865 (with Elizabeth Cary Agassiz, his father's wife) *Seaside Studies in Natural History*, a work at once exact and stimulating, and in 1871 a volume on the *Marine Animals of Massachusetts Bay*.

Agen, chief town of department Lot-et-Garonne, France, 380 miles S.S.W. of Paris, on railway from Bordeaux to Cette. The Garonne is here crossed by a suspension and two stone bridges; one of the latter, a fine structure of twenty-three arches, carries the lateral canal. Amongst the public buildings are the cathedral of St Caprais (who introduced Christianity in the 3rd century), parts of which date from the 12th and 13th centuries, and the ancient church of the Jacobins. The industries include the manufacture of drugs and pottery, and there are phosphate and dye works. Agen is noted for fine prunes, in which, as well also in other fruits, it carries on considerable trade. It was the birthplace of Joseph Scaliger the philologist, the naturalist Lacepède, and the poet Jacques Boé, better

known as Jasmin. Population (1881), 17,098; (1891), 18,463; (1896), 18,389.

Aggregation, States of. See CONDENSATION OF GASES.

Agira, formerly SAN FILIPPO D'ARGIRÒ, a town of the province of Catania, Sicily, Italy, 9 miles S.E. from Nicosia, standing 2133 ft. above sea-level, with sulphur mines and flour-mills. It is the ancient *Argyrium*, one of the oldest of the Sicilian towns, and was colonized by Timoleon, the liberator of Syracuse, in 339 B.C. It was the birthplace of the historian Diodorus Siculus (1st cent. B.C.). Population 13,498 (1881); 17,749 (1901).

Agnew, David Hayes (1818-1892), American surgeon, was born in Lancaster county, Pennsylvania, on 24th November 1818. He graduated from the medical department of the University of Pennsylvania in 1838, and a few years later set up in practice at Philadelphia and became a lecturer at the Philadelphia School of Anatomy. He was appointed surgeon at the Philadelphia Hospital in 1854, and was the founder of its pathological museum. For twenty-six years (1863-89) he was connected with the medical faculty of the University of Pennsylvania, being elected professor of operative surgery in 1870 and professor of the principles and practice of surgery in the following year. From 1865 to 1884—except for a brief interval—he was a surgeon at the Pennsylvania Hospital. During the American Civil War he was consulting surgeon in the Mower Army Hospital, near Philadelphia, and acquired considerable reputation for his operations in cases of gunshot wounds. He attended as operating surgeon when President Garfield was fatally wounded by the bullet of an assassin in 1881. He was the author of several works, the most important one being a three-volume, *The Principles and Practice of Surgery*. He died at Philadelphia on 22nd March 1892.

Agnosticism.—The term "agnostic" was invented by Huxley in 1869 to describe the philosophical and religious attitude of those who hold that we can have scientific or real knowledge of phenomena only, and that so far as what may lie behind phenomena is concerned—God, immortality, &c.—there is no evidence which entitles us either to deny or affirm anything. The attitude itself is as old as Scepticism (*q.v.*); but the expressions "agnostic" and "agnosticism" were applied by Huxley to sum up his deductions from those contemporary developments of metaphysics with which the names of Hamilton ("the Unconditioned") and Herbert Spencer ("the Unknowable") were associated; and it is important, therefore, to fix precisely his own intellectual standpoint in the matter. Though Huxley only began to use the term "agnostic" in 1869, his opinions had taken shape some time before that date. In a letter to Charles Kingsley (23rd September 1860) he wrote very fully concerning his beliefs:—

I neither affirm nor deny the immortality of man. I see no reason for believing it, but, on the other hand, I have no means of disproving it. I have no *a priori* objections to the doctrine. No man who has to deal daily and hourly with nature can trouble himself about *a priori* difficulties. Give me such evidence as would justify me in believing in anything else, and I will believe that. Why should I not? It is not half so wonderful as the conservation of force or the indestructibility of matter. . . .

It is no use to talk to me of analogies and probabilities. I know what I mean when I say I believe in the law of the inverse squares, and I will not rest my life and my hopes upon weaker convictions. . . .

That my personality is the surest thing I know may be true. But the attempt to conceive what it is leads me into mere verbal subtleties. I have champed up all that chaff about the ego and the non-ego, noumena and phenomena, and all the rest of it, too often not to know that in attempting even to think of these

questions, the human intellect flounders at once out of its depth.

And again, to the same correspondent, 5th May 1863:—

I have never had the least sympathy with the *a priori* reasons against orthodoxy, and I have by nature and disposition the greatest possible antipathy to all the atheistic and infidel school. Nevertheless I know that I am, in spite of myself, exactly what the Christian would call, and, so far as I can see, is justified in calling, atheist and infidel. I cannot see one shadow or tittle of evidence that the great unknown underlying the phenomenon of the universe stands to us in the relation of a Father—loves us and cares for us as Christianity asserts. So with regard to the other great Christian dogmas, immortality of soul and future state of rewards and punishments, what possible objection can I—who am compelled perforce to believe in the immortality of what we call Matter and Force, and in a very unmistakable *present* state of rewards and punishments for our deeds—have to these doctrines? Give me a scintilla of evidence, and I am ready to jump at them.

Of the origin of the name “agnostic” to cover this attitude, Huxley gave (*Coll. Ess.* v. pp. 237-239) the following account:—

When I reached intellectual maturity, and began to ask myself whether I was an atheist, a theist, or a pantheist, a materialist or an idealist, a Christian or a freethinker, I found that the more I learned and reflected, the less ready was the answer. The one thing on which most of these good people were agreed was the one thing in which I differed from them. They were quite sure they had attained a certain “gnosis”—had more or less successfully solved the problem of existence; while I was quite sure that I had not, and had a pretty strong conviction that the problem was insoluble. This was my situation when I had the good fortune to find a place among the members of that remarkable confraternity of antagonists, the Metaphysical Society. Every variety of philosophical and theological opinion was represented there; most of my colleagues were *-ists* of one sort or another; and I, the man without a rag of a belief to cover himself with, could not fail to have some of the uneasy feelings which must have beset the historical fox when, after leaving the trap in which his tail remained, he presented himself to his normally elongated companions. So I took thought, and invented what I conceived to be the appropriate title of “agnostic.” It came into my head as suggestively antithetic to the “gnostic” of Church history, who professed to know so much about the very things of which I was ignorant. To my great satisfaction the term took.

This account is confirmed by R. H. Hutton, who in 1881 wrote that the word “was suggested by Huxley at a meeting held previous to the formation of the now defunct Metaphysical Society at Mr Knowles’s house on Clapham Common in 1869, in my hearing. He took it from St Paul’s mention of the altar to the Unknown God.” Hutton here gives a variant etymology for the word, which may be therefore taken as partly derived from *ἄγνωστος* (the “unknown” God), and partly from an antithesis to Gnostic; but the meaning remains the same in either case. The name, as Huxley said, “took”; it was constantly used by Hutton in the *Spectator*, and became a fashionable label for contemporary unbelief in Christian dogma, particularly during the ’seventies and ’eighties. Hutton himself frequently misrepresented the doctrine by describing it as “belief in an unknown and unknowable God”; but agnosticism as defined by Huxley meant not belief, but absence of belief, as much distinct from belief on the one hand as from disbelief on the other; it was the half-way house between the two, where all questions were “open.” All that Huxley asked for was evidence, either for or against; but this he believed impossible to get. Occasionally he too mis-stated the meaning of the word he had invented, and described agnosticism as meaning “that a man shall not say he knows or believes what he has no scientific ground for professing to know or believe.” But as the late Rev. A. W. Momerie remarked, this would merely be “a definition of honesty; in that sense we ought all to be agnostics.” Agnosticism really stands or falls by the doctrine of the Unknowable, the assertion that concerning certain objects—

among them the Deity—we never can have any “scientific” ground for belief. In the ’seventies and ’eighties this way of solving, or rather passing over, the ultimate problems of thought had many followers in cultured circles imbued with the new science of the day, and with disgust for the dogmatic creeds of contemporary orthodoxy; and its outspoken and even aggressive vindication by physicists of the eminence of Huxley had a potent influence upon the attitude taken towards metaphysics, and upon the form which subsequent Christian apologetics adopted. As a nickname the term agnostic was soon misused to cover any and every variation of scepticism, and just as popular preachers confused it with atheism in their denunciations, so the callow freethinker—following Tennyson’s path of “honest doubt”—classed himself with the agnostics, even while he combined an instinctively Christian theism with a facile rejection of the historical evidences for Christianity.

Huxley’s agnosticism was a natural consequence of the intellectual and philosophical conditions of the ’sixties, when clerical intolerance was trying to excommunicate scientific discovery because it appeared to clash with the book of Genesis. But as the theory of evolution did its work, a new spirit was gradually introduced into Christian theology, which has turned the controversies between religion and science into other channels, and taken most of the wind out of the sails of agnosticism. A similar effect has been produced by the philosophical reaction against Herbert Spencer, and by the perception that the canons of evidence required in physical science must not be exalted into universal rules of thought. It does not follow that justification by faith must be eliminated in spiritual matters, where sight cannot follow, because the physicist’s duty and success lie in pinning belief solely on verification by physical phenomena, when they alone are in question; and for mankind generally, though possibly not for an exceptional man like Huxley, an impotent suspension of judgment on such issues as a future life or the Being of God is both unsatisfying and demoralizing.

It is impossible here to do more than indicate the path out of the difficulties raised by Huxley in the letter to Kingsley quoted above. They involve an elaborate discussion, not only of Christian evidences, but of the entire subject-matter alike of Ethics and Metaphysics, of Philosophy as a whole, and of the philosophies of individual writers who have dealt in their different ways with the problems of existence and epistemology. It is, however, permissible to point out that, as has been exhaustively argued by Professor J. Ward in his Gifford lectures for 1896-98 (*Naturalism and Agnosticism*, published by A. & C. Black, 1899, London), Huxley’s challenge (“I know what I mean when I say I believe in the law of the inverse squares, and I will not rest my life and my hopes upon weaker convictions”) is one which a spiritualistic philosophy need not shrink from accepting at the hands of naturalistic agnosticism. If, as Huxley admits, even putting it with unnecessary force against himself, “the immortality of man is not half so wonderful as the conservation of force or the indestructibility of matter,” the question then is, how far a critical analysis of our belief in the last-named doctrines will leave us in a position to regard them as the last stage in systematic thinking. It is the pitfall of physical science, immersed as its students are apt to be in problems dealing with tangible facts in the world of experience, that there is a tendency among them to claim a superior status of objective reality and finality for the laws to which their data are found to conform. But these generalizations are not ultimate truths, when we have to consider the nature of experience itself. “Because reference to the Deity will not serve for a physical explanation in physics, or a

chemical explanation in chemistry, it does not therefore follow," as Professor Ward says (*op. cit.* vol. i. p. 24), "that the sum total of scientific knowledge is equally intelligible whether we accept the theistic hypothesis or not. It is true that every item of scientific knowledge is concerned with some definite relation of definite phenomena, and with nothing else; but, for all that, the systematic organization of such items may quite well yield further knowledge, which transcends the special relations of definite phenomena." At the opening of the era of modern scientific discovery, with all its fruitful new generalizations, the still more highly generalized laws of epistemology and of the spiritual constitution of man might well baffle the physicist and lead his intellect to "flounder"; but Logic too is capable of advancing, and with a superior Logic the new premisses supplied by the revelations of science are not inconclusive to those who patiently follow truth.

Agra, a city of British India, in the North-west Provinces, which also gives its name to a district and a division. The city, on the right bank of the Jumna, 841 miles from Calcutta, is now an important railway centre, whence two main lines diverge southwards towards Bombay. In 1872 the population was 149,008; in 1881 it was 160,203; in 1891 it was 168,662; in 1901 it was 188,300, showing an increase of 12 per cent. The death-rate in 1897 was 52 per thousand. It has 2 cotton mills, with 24,450 spindles, employing 1200 hands; 7 factories for ginning and pressing cotton; a tannery and boot factory; flour mill; 48 printing presses. In 1896-97 the government college had 194 students. There are also two missionary colleges. The native town is well laid out and handsomely built. Only a small garrison is now kept in the cantonment. The municipality consists of 34 members, of whom 24 are elected, with the magistrate as *ex officio* chairman. The water-works provide a daily consumption of 1,338,000 gallons, being 8 gallons per head in the town, and 11½ gallons in the cantonment. The municipal income in 1896-97 amounted to Rs. 3,82,388.

The district of AGRA is traversed by several lines of railway, and part of it is irrigated by the Agra Canal. Land revenue and rates (1896-97) amounted to Rs. 19,74,298, the incidence of assessment being R. 1:12 per acre; the cultivated area was 683,111 acres, of which 313,728 were irrigated from wells, &c.; the number of police was 3753; of vernacular schools, 153, with 5265 pupils; the registered death-rate in 1897 was 56 per thousand. The principal crops are millets, pulses, barley, wheat, cotton, and a little indigo. Area, 1845 square miles; population (1891), 1,003,796, being 544 persons per square mile; (1901), 1,060,546, showing an increase of 6 per cent.

The division of AGRA has an area of 10,139 square miles. In 1891 the population was 4,767,759, being 470 persons per square mile. In 1901 the population was 5,248,121, showing an increase of 10 per cent., attributed to the extension of irrigation from canals. It comprises the six districts of Muttra, Agra, Farukhabad, Mainpuri, Etawah, and Etah.

Agram (Slavonic, *Zagrab*; Croatian, *Zagreb*), a municipal town of Hungary, the capital of the provinces of Croatia and Slavonia. Population (1890), 38,742; (1900), 57,930. It is the seat of an archbishop and a university. The inhabitants carry on a brisk commerce and industry,

its more considerable establishments being a tobacco manufactory, the works of the Hungarian state railways, a leather manufactory, a manufactory of war articles and one of carpets, &c. The new streets, especially in the lower town, are very fine, with numerous large mansions and excellent statues. The scientific and financial institutions are rapidly acquiring a recognized status.

Agricultural Machinery.—Since 1875 there has been a marked advance in agricultural machines—not so much in the invention of machines wholly unknown prior to that time, but rather in the constant improvement of those which then existed. So gradual, however, has been the change that it is hardly possible, except in the case of the Self-binding Harvester, to point to any single invention as showing a great departure from the general lines of development, though the final results are very apparent when the simple, strong, and effective machines of to-day are compared with those of a quarter of a century ago. Under these circumstances it seems undesirable to treat the subject historically, and we shall therefore illustrate and describe one or more types of the latest machines in each important class, leaving the reader to judge for himself the extent of the advance since the article in the ninth edition of this work (vol. i. p. 311) was written.

American implement makers have gone far ahead of Europe or the United Kingdom, and the following article is accordingly written from an American standpoint, and does not represent the actual conditions in operation in more conservative countries (see, however, p. 208 below). The several classes of machines will be treated by describing them in the order in which they are used in carrying on the operations performed: 1st, ploughing; 2nd, the preparation of the seed-bed; 3rd, seeding or planting; 4th, cultivating; 5th, harvesting.

Ploughs.

Where the amount of work to be done is small, and the character of the farm does not permit the use of the riding plough, the old, familiar walking plough is still in use; but it has several serious defects. Owing to the fact that the friction between the earth and the plough is entirely a sliding friction, the character of material employed in constructing the plough, and the finish imparted to it, and also the form given to the parts, have a very important effect in determining the force required to carry on the operation; and it is in respect of these features that most of the improvements in this style of implement have been made. Instead of cast iron, left in the rough state as it comes from the mould, the mould-board is now made of steel, well tempered and highly polished, the result of which is to improve its scouring qualities, and greatly reduce the draft necessary to operate it. The use of this form of plough calls for considerable skill and strength in holding it to its work, and the attention of the inventor has been naturally turned to the production of a machine in which these objections are obviated; and on the larger farms, and where the character of the surface permits it, the *sulky* or riding plough is now generally used¹ (see Fig. 1).

In this form of plough the frame is mounted on three wheels, one of which runs on the land, and the other two in the furrow. The furrow wheels are placed on inclined axles, the plough beam being carried on swinging links, operated by a hand lever when it is necessary to raise the plough out of the furrow. The land wheel and the for-

¹ *Sulky* machines for tilling this soil are not used in the United Kingdom. The driver is not seated, in the case of ploughs, harrows, cultivators, rollers, etc.; but mowing machines, hay makers, harvesters, &c., have a seat for the driver, as in the United States.

ward furrow wheel are adjustable vertically with reference to the frame, for the purpose of controlling the action of the plough. The team is hitched to a clevis at the end of the plough beam, and the machine is guided by a pole secured to an arm on the upper end of the spindle of the forward furrow wheel; and, by means of a connexion between this arm and a controlling arm on the spindle of the rear wheel, the latter is controlled in turning by the former.

The sulky plough has important advantages over the walking plough from the fact that the weight and downward pull due to its action on the ground are taken by

FIG. 1.—Sulky plough.

the wheels, and the friction, being thus converted from sliding into rolling friction, is much less, and the draft is correspondingly diminished. It is also easily guided, and the depth of the furrow is readily controlled by the levers, which are assisted in their action by springs, thus greatly lightening the labour. The walking plough also possessed a serious defect on account of the downward pressure on the bottom of the furrow, which not only added to the friction, but had the effect of forming a hard and smooth bottom, which served to turn water, causing it to run along the bed thus formed and wash away the fertile soil. This was remedied to some extent by the sulky plough, as the bottom pressure was taken up by the wheels; but a form of plough intended to overcome this defect is being introduced into extensive use.

This plough is built both as a riding and a walking plough, and is shown in Fig. 2. The essential feature is the substitution of a concavo-convex disk, pivoted on the plough beam, for the mould-board and share of the ordinary plough. This disk is carried on an axle inclined to the line of draft, and also to a vertical plane. As the machine is drawn forward the disk turns on its axis and cuts deeply into the ground, and, by reason of its inclination, crowds the earth outwards and thus turns a furrow. A scraper is provided to keep the disk clean and prevent sticking, and a small plough in the rear squares the corner of the furrow. The controlling levers and draft arrangements are similar to those already described in connexion with the sulky plough. The advantage of this plough over the ordinary form is in the absence of sliding friction, and in the mellow and porous condition in which it leaves the bottom of the furrow.

Variations in soil and in the character of the surface of farming lands have led to various modifications of the plough to suit it to these different conditions. In cases where the soil is hard and clayey, it is desirable to plough

deeper than usual, and for this purpose a subsoiling plough is used, which does not turn a furrow, but digs deeply into the ground and thoroughly stirs it.

FIG. 2.—Disk plough.

Where a hillside is to be worked, a swivel plough (Fig. 3) is used. In this machine the mould-board is symmetrical about a line drawn from its point to the middle of its rear end, and is pivoted at its front and

FIG. 3.—Swivel plough.

rear to the landside, so that it can be swung underneath from one side to the other, and thus changed from right to left hand, in order that the furrow may be always turned down hill.

Preparation of the Seed-Bed.

The ground having been ploughed, it becomes necessary to pulverize it and break up the clods to furnish a good seed-bed, and for this purpose the harrow is used.

Harrows.—The oldest and simplest form of harrow consisted of a frame of wood, having on its under side a number of teeth, which, as the implement was drawn over the ploughed field, combed or raked the surface until it was substantially level. The first step in improving this harrow consisted in building the frame of steel bars and forming them in two or more sections secured to a common draft bar by flexible connexions, thus enabling the harrow to accommodate itself more exactly to the inequalities of the ground, and to secure a more perfect result. A harrow of this type is shown in Fig. 4.

In this machine the teeth are secured to bars pivoted at their ends in the side bars of the frame, and provided with crank arms connected to a common link bar, which may be moved horizontally by means of a lever for the purpose of

adjusting the angle which the teeth make with the ground, and thus convert the machine from a pulverizer to a smoothing harrow. The small figure illustrates a spring connexion between the adjusting lever and its locking

FIG. 4.—Harrow.

Showing tooth mechanism of harrow.

bar, which allows the teeth to yield upon striking an obstruction.

The course of improvement of the harrow has been much the same as in the plough, *i.e.*, in so constructing it that the operator may ride and control its movements with ease from his seat on the machine.

FIG. 5.—Spring-tooth harrow.

Fig. 5 illustrates a spring-tooth harrow arranged for riding. In this harrow the independent frames are carried upon wheels, and a seat for the operator is mounted upon standards supported by the two frames. The teeth consist of flat steel springs of scroll form, which

before described. The levers enable the operator to raise the teeth more or less, and thus free them from trash, and also regulate the depth of action.

The next improvement of the harrow is illustrated in Fig. 6.

FIG. 7.—Roller pulverizer.

This machine consists of a main frame, having a pole and whiffle-trees attached, and to this frame are pivoted, near their outer ends, two supplemental frames, each of which has mounted therein a shaft carrying a series of concavo-convex disks. The supplemental frames may be swung by the adjusting levers to any angle with relation to the line of draft, and the disks then act like that of the disk plough, throwing the soil outward with more or less force, according to the angle at which they are set, and thus thoroughly breaking up and pulverizing the clods. Above the disks is a bar to which are pivoted a series of scrapers, one for each disk, which are held to their work with a yielding action, being thrown out of operation when desired by the levers shown in connexion with the operating bar. The pans on the main frame are used to carry weights to hold the disks down to their work.

For the purpose of more thoroughly pulverizing the soil, a roller is frequently used, and an improved form of this implement is shown in Fig. 7.

It consists of a set of skeleton rollers carried on a shaft, and revolving freely in such a manner that the longitudinal bars break up all lumps as the roller passes over them.

One of the hardest and most disagreeable tasks of the farmer is the hauling and distribution of manure and fertilizers; and for the purpose of lightening his labours in this respect a machine has been produced (see Fig. 8).

FIG. 6.—Disk harrow.

yield to rigid obstructions, and are mounted on rock shafts in the same manner as in the walking harrow

for the purpose of lightening his labours in this respect a machine has been produced (see Fig. 8).

It consists of a waggon, the bottom of which is formed by a travelling bed or apron driven by suitable connexions

FIG. 8.—Fertilizer distributor.

with the wheels of the waggon. At the rear is mounted a revolving spiked drum or cylinder, which tears up and distributes the fertilizer as it is fed by the apron.

Seeders and Planters.

The soil having been prepared, the next step is to sow the seed, and this is done either by broadcasting, drilling, or planting in hills.

FIG. 9.—Broadcast seeder.

The broadcast seeder (see Fig. 9) consists of a wheeled frame carrying transversely thereto a seed-box having a number of seed-cups in its bottom into which the seed falls, and extending through these cups is a shaft carrying feed-wheels, one for each seed-cup. These feed-wheels are similar to a common spur gear, and serve to feed the seed regularly and deposit it in the downwardly extending tubes, where it falls upon an inclined plate and is scattered in all directions. The feed-shaft is made longitudinally

FIG. 10.—Broadcast seeder.

adjustable; and draws the feed-wheels in or out through a revolving washer in the side of the feed-cups, thus exposing more or less of the width of the teeth and regulating the quantity of seed carried thereby.

A very convenient and cheap form of broadcast seeder is shown in Fig. 10.

This machine consists of a seed-hopper, mounted on a special tail-board, which can be substituted for the one generally used by the farmer on his waggon; a driving shaft, also mounted thereon and connected by a sprocket-chain with a sprocket-wheel on one of the rear wheels of the waggon; a rotating seed-plate in the bottom of the hopper; and a distributing wheel, shaped much like a windmill, upon which the grain falls. The seed is very effectively scattered from the distributing wheel by centrifugal force.

Machines used for drilling the seed in rows are substantially like the broadcast seeder, except that the seed falls from the tubes into a boot, as illustrated in Fig. 11.

FIG. 11.—Grain drill.

Each of these boots is carried on an arm hinged at its forward end to the main frame, and provided at its lower end with a hoe, which makes a shallow furrow for the seed.

In some of the latest machines other forms of furrow-making devices are substituted for the hoes, and two of these variations are illustrated in Figs. 12 and 13.

FIG. 12.—Shoe furrower.

In Fig. 12 the furrow is formed by a shoe consisting of two plates converging at their forward ends, and spaced apart immediately beneath the boot, through which the seed falls into the furrow.

In Fig. 13 the furrowing tool is the concavo-convex disk, set at an angle to the line of draft as in the disk plough, and the seed is dropped into a space formed between the disk and a flat plate secured to the lower end of the boot and bearing against the concave face of the disk.

In the United States the maize or Indian-corn crop¹ exceeds all others in value, and machines used in planting and handling this crop are of great importance. Corn (maize) is sometimes listed or planted in a continuous row like wheat, and for this purpose a machine

FIG. 13.—Disk furrower.

known as a lister is employed, which is shown in Fig. 14.

FIG. 14.—Maize lister.

In its general construction this machine is a sulky plough, having a double mould-board, which turns the furrow in both directions. Immediately behind the plough is a sub-soiler for deepening the furrow and penetrating to the moist soil below the surface. A seed-box is mounted on the plough beam, and is provided with a feed-plate operated by a shaft geared to one of the wheels. The seed is delivered to the furrow in rear of the sub-soiler and covered by two shovels which turn the soil back into the furrow.

FIG. 15.—Check row corn planter.

It is, however, more common to plant maize in hills, which are spaced equally from each other and form rows

in both directions, so that a cultivator may be driven between them. This work is done by a machine called a check row corn planter, shown in Fig. 15.

In using the corn planter, a wire, having buttons attached thereto, at intervals corresponding to the distance between the hills, is first stretched across the field and anchored at its ends. This wire is then placed upon the guide rollers at the side of the machine and passes between the jaws of a forked lever, which is connected at its other end with a rock-shaft passing across the machine and

FIG. 16.—Check row corn planter.

serving to oscillate a feed-plate in the bottom of each seed-hopper. As the buttons on the check-wire strike the forked lever, the latter is drawn to the rear and causes the feed-plate to drop the seed through the tubes into the open space between the plates of the furrowing shoe. The reel at the rear of the machine is used to take up the check-wire as the planter progresses.

In one of the latest corn planters, shown in Fig. 16, the check-wire is dispensed with, and the machine is provided with a shaft carrying two reels, the blades of which are at a distance apart equal to the distance between the hills of corn, and thus measure the intervals at which the corn is to be dropped. A rod, extending from the side of the machine, and carrying a small wheel, marks the next row and serves as a guide to the driver.

Potatoes are also planted by a special machine, which may be seen in Fig. 17.

FIG. 17.—Potato planter.

The potato planter consists of a frame mounted on wheels, carrying a seed-box and usually a receptacle for fertilizers. The potatoes are fed by a suitable valve-plate into a chamber in which revolves a wheel having at the extremities of its spokes pins which impale the potatoes one by one, and carry them over to the seed tube, through which they fall into the furrow opened for them by a shoe, in the same manner as in the corn planter. An endless

¹ In America the word "corn" usually signifies maize, not wheat—as in the United Kingdom—and so throughout this article. As a grain crop maize can only be grown in Europe in the southern parts and in the Danube valley.

apron feeds the fertilizer and drops it with the potatoes, the furrow being closed by a pair of disks which follow the seed tube.

Cultivators and Weeders.

It is important, after the seed has been planted and sprouted, to keep the ground in a porous condition, in order that it may absorb and retain moisture, and be easy of penetration by the growing roots. This result is

Fig. 18.—Cultivator.

attained by the use of cultivators, and their construction will be easily understood from Fig. 18.

Fig. 19.—Disk cultivator.

These machines are made as walking cultivators; but, as in all the implements before described, the tendency is to provide a machine upon which the operator may ride. The drawing shows one adapted for either mode of opera-

Fig. 20.—Weeder.

tion. It comprises an arched axle, to extend over the row

of plants; a draft frame, secured to the axle; and a pair of cultivator frames, carrying small shovels for breaking up the soil. These cultivator frames are hinged at their forward ends to the main frame, and are supported by springs, so that they would be normally raised from the ground; but the necessary pressure is applied by the feet of the rider, or by the hands of the operator in case he is walking behind the machine.

The latest forms of the cultivator, as shown in Fig. 19, substitute for the shovels two sets of concavo-convex disks, operating precisely as in the disk plough and harrow before mentioned.

Fig. 20 shows a new type of weeding machine now coming into use, and consisting of a wheeled frame, to which the team is attached, and from which depend a number of spring wires, whose action is to rake and tear out the weeds. A lever permits the operator to adjust the angle of the teeth with the ground.

Fig. 21.—Combination implement.

In Fig. 21 is shown a very interesting implement, which is intended for gardeners, and is pushed by the operator. By changing one part for another, by simply detaching them and making the necessary substitution, the machine may be used as a hill or drill seeder and marker, a plough, a wheel hoe, a cultivator, and a harrow or rake.

Harvesters.

Mowing machines have long been in use, but have been constantly improved in construction, and the modern machine far exceeds in durability and convenience of

Fig. 22.—Mower.

operation that which was in use a few years ago. It is now made almost entirely of iron and steel, with very

little wood, and this construction enables all joints to be made much stronger and more permanent. bars, which extend rearwardly between the teeth, prevent the hay from clinging and ensure its discharge.

A recent form of mower is shown in Fig. 22. The cutter bar is of the well-known type. The draft evener slides in guides upon the tongue, and is connected with the coupling bar in such a manner that the weight of the entire cutting apparatus is taken off the ground, thus producing a very light running machine. Levers are provided for tilting the finger bar for cutting closer or higher, and a second lever raises the coupling frame and finger bar in passing obstructions. The latter operation may also be performed by the foot of the operator pressing upon the curved lever at the rear of the axle.

FIG. 25.—Side delivery horse rake.

In Fig. 25 is shown what is known as a side-delivery horse rake, which takes up the hay by means of a revolving toothed cylinder, from which it is taken by a toothed carrier and delivered upon a transversely moving apron. The hay is thus discharged from the machine in a continuous wind-row, extending in a direction parallel with the line of draft of the machine.

Another labour-saving machine is the tedder (Fig. 26) used for spreading and turning the hay while it is being cured.

FIG. 23.—Lawn mower.

For mowing lawns, the machine shown in Fig. 23 is used.

Instead of a reciprocating knife, the lawn mower employs a revolving reel, having spirally-arranged knives which impinge upon a stationary knife and cut the grass with a shearing action which is more effective in short and tender grass than a reciprocating knife. The gauge roller at the rear of the machine regulates the height of the cut.

Instead of raking hay by hand, the farmer now employs a horse rake, which is illustrated in Fig. 24.

The hay is raked by the spring teeth, and when a sufficient quantity to form a wind-row has accumulated, the driver presses with his foot upon a lever operating a clutch and connecting the rake head to the driving wheels. The rake is thus raised and the

FIG. 26.—Hay tedder.

This machine is mounted on two wheels, and carries in bearings at the rear of the frame a multiple-cranked shaft, provided with a series of forks sleeved on the cranks and having their upper ends connected by links to the frame. As the crank-shaft is driven from the wheels by proper gearing the forks move upward and forward, then downward and rearward, in an elliptical path, and kick the hay sharply to the rear, thus scattering and turning it. The tedder forks are hinged to the arms and are provided with cranks connected by rods to springs on the arms, being thus enabled to yield and avoid breakage by striking an obstacle.

For loading the hay on waggons a combined hay rake and loader, shown in Fig. 27, may be used.

This machine is coupled to the rear of the hay-rack and is drawn over the field, the revolving hay rake picking up the hay and feeding it to the elevator, which consists of

FIG. 24.—Horse rake.

load dumped by the action of the team. The clearer

In storing hay in the barns the work may be done by | in this manner much storage space is saved, and, in a travelling carrier running on tracks above the hay mow, | shipping, the freights are greatly reduced. In fact, it

If the hay is to be stacked, a drag-rake and stacker, as shown in Fig. 28, may be employed.

The drag-rake consists of a triangular frame, having a supporting wheel at each angle, and a rake head pivoted to the frame parallel with the base of the triangle. The rake head can be lowered so that the teeth sweep the ground and take up a large quantity of hay. The rake is then driven to the stacker and the load is deposited on the elevating rake, which is hoisted by a system of pulleys and ropes, and discharges the hay on to the stack.

If hay is to be shipped it is advantageous to bale it, a press operated by horse-power (Fig. 29) being used for the purpose.

The hay-press is provided with a hopper into which the loose hay is fed in front of a plunger moved by means of a lever, to which the horses are attached. The action of the lever is then reversed, the plunger retreats, a new charge of hay is fed, and the movement is repeated. In this way the hay is pressed into a compact bale, wires are passed around it and secured, and the bale is then ejected. By treating the hay

FIG. 28.—Drag-rake and stacker.

the hay being removed from the waggon by means of a | harpoon fork or by slings upon which it is laid when put |

in the waggon. The fork or slings are attached to the | would be impossible to ship hay to any distance unless pulley of the carrier, and the load is elevated and carried | it were baled.

Potatoes are, perhaps, most often dug by hand, but there are also machines and implements provided for this purpose.

One of the simplest of potato diggers (Fig. 30) consists of a double plough, to each wing of which are secured rearwardly extending fingers. As the plough is drawn through the field, the potatoes are thrown up, and as they slide over the fingers the loose earth is sifted through, while the potatoes fall off at the rear upon the surface of the ground, from which they are picked up by hand.

FIG. 31.—Potato digger.

A slightly different form of digger is shown in Fig. 31. This plough throws up the potatoes like the former one, but turns them off on each side, where they fall upon a floating frame composed of steel rods, which are caused to vibrate by the inequalities of the ground, sifting out the earth and leaving the potatoes on the surface.

FIG. 32.—Potato digger.

A more complicated form of potato digger is shown in Fig. 32. This machine is designed to be drawn by a pair of horses, and carries at its forward end a powerful scoop, which takes up the earth and potatoes, delivering them upon an endless carrier driven from the wheels of the machine. This carrier is composed of rods, and is given a vibrating motion by which most of the earth is sifted out, and the potatoes are discharged upon a second carrier which completes the operation. The scoop can be adjusted by a suitable lever to dig at any desired depth.

Grain Harvesters.

Twenty-five years ago grain was harvested by machines, but they were very different in character from those now in use, and in no class of agricultural machines has in-

vention made so great a change. Most of the grain was then harvested by machines cutting by a reciprocating knife and throwing the grain upon a travelling canvas apron, which delivered it to a second elevator apron carrying it over the driving wheel, where it was dropped upon a table and bound by an attendant. These machines were furnished with a divider at the end of the cutter bar for separating the grain to be cut from the standing grain, and also with a reel which pressed forward into the standing grain and pushed it back to present it properly to the cutter bar. All these are essential features of the modern harvester.

About 1873, what was probably the first commercially successful automatic self-binding harvester was brought out in the Locke wire binder. This was extensively used for several years, and wire binders were also built by other manufacturers, but there were serious objections to their use, principally on account of pieces of the wire being carried into the threshing machines and even into the flour-mills, where, by contact with the rapidly moving machinery, they were likely to cause fires.

The attention of inventors was then turned to the twine binder, but although some of the earliest attempts at grain binding were made with twine, even antedating the wire binders, it was not until 1879 that the Appleby patent, under which most of the self-binding harvesters of to-day are built, was taken out; and it was not until several years later that they came into extensive use. Some of the most important parts of the binder had been invented

before the Appleby patent, such as the automatic trip which regulates the action of the binder, invented by Gray in 1858, and the knotting bill and revolving cord-holder, patented by Behel in 1864. For various reasons, however, none of these inventions went into use until they were embodied in the Appleby machine. The self-binding harvester is probably the most ingenious and interesting of all agricultural machines, and will be briefly described.

Fig. 33 shows a rear view of the self-binding harvester. As already explained, the grain is bent over and presented to the reciprocating cutter bar by means of the revolving reel, and is then conveyed by the apron and elevator over the master wheel and discharged upon the downwardly inclined binder table.

FIG. 33.—Self-binding harvester.

As the grain flows from the elevator, the butts are at the front of the machine and are evened up by a device called a butt adjuster, shown in Fig. 34, which is connected to a crank at its upper end and guided on a rod at its lower end, being thus given an elliptical movement and patting the ends of the grain, thus squaring the butt of the sheaf.

The grain moving on down the binder deck is forwarded by the packers, as seen in Fig. 35. These consist of a

FIG. 34.—Butt adjuster.

pair of arms sleeved upon cranks on a constantly driven shaft, and having their lower ends connected by links to

FIG. 35.—Binding mechanism.

the frame of the machine. By means of the packers, the grain is forced against the compressor or trip arm until a

FIG. 36.—Knot-tying mechanism.

sufficient quantity has accumulated to form a bundle, the size of which is regulated by suitable adjusting devices. When the pressure on the trip arm becomes sufficient to

overcome the tension of the spring, shown at the right of the figure, the latter yields, and the trip latch, being connected to the compressor shaft, is raised and releases the end of a dog carried on a gear by which the knotter shaft is driven, and the dog is immediately thrown down by a spring engaging a lug on the packer shaft. This starts the knotter shaft, which carries the compressor cam, and the cam wheel being connected by a pitman with the needle shaft, the needle moves upward, passing the cord round the bundle. Simultaneously with the motion of the needle, the compressor is forced against the grain, and the bundle is tightly compressed between the compressor and the needle, thus taking most of the strain off the cord.

Previously to the upward movement of the needle, the cord is held by one end in the cord holder, which lies outside the knotter bill, as seen in Figs. 36 and 37, and extends

FIG. 37.—Knot-tying mechanism.

over the knotter, underneath the bundle, through the eye of the needle, and thence to the twine box. As the needle carries the cord upward, the second strand is laid over the knotter and cord holder, and, at this moment, the segmental racks on the knotter wheel engage the pinions of the knotter and cord holder. As the knotter rotates, a loop of both strands of the cord is formed round both jaws, and when about three-quarters of the revolution is completed, the upper jaw is raised by a cam, the strands between the knotter and cord holder passing between the

FIG. 38.—Holmes binder.

jaws and being grasped thereby. The cord-holder disk carries a knife which now strikes the cord and severs it, the end running to the eye of the needle remaining in the grasp of the holder. The discharger arms, which are rigidly secured to the knotter wheel, then reach the bundle, forcing it out of the binder, drawing off the loop from the knotter over the bight held between its jaws, and the knot is complete. All this takes place during a single revolution of the knotter shaft, and as

the needle retreats, the trip latch is lowered into position to strike the trip dog, thus releasing it from the lug on the packer shaft and stopping the binder until the next bundle is formed, when the action is repeated.

FIG. 39.—Holmes binder.

As the bundles are discharged from the binder, they are received by a bundle carrier and retained until it contains the number necessary to form a shock, when the carrier is tripped by the operator and the sheaves are deposited upon the ground. The bundle carrier is an important addition to the binder, and the cost of labour in setting the sheaves in shocks is lessened, as they are deposited in a single spot instead of being gathered from a considerable area.

The only binder built in the United States differing from the Appleby type is the Holmes binder, illustrated by Figs. 38 and 39.

This binder differs in its general organization from the Appleby, the packers being of the toothed disk type and carried above the binder table, as is also the starting clutch. The discharger is similar in construction to the forks of a tedder. The knotter is composed of two parts carried by a rotary spindle, one of them being

The cord holder is of the sliding jaw type instead of the rotary form.

On small farms, the sweep-rake reaper shown in Fig. 40 is frequently used.

The cutting apparatus of this machine is similar to that in all harvesting machines, but is attached to the front of a quadrantal platform upon which the grain falls as it is cut. At the stubbleward end of the frame, just inside the master wheel, is a pedestal having upon its top a cam. A rotating shaft carrying a number of rake arms, hinged thereto, is mounted in the pedestal, and the rake arms are guided by the cam in such a manner that they bring the grain to the cutter bar, sweep it back over the platform, depositing it in a gavel on the ground, and are then raised abruptly to clear the driver. These cams can generally be set by a switch, so that every rake, or every second, third, or fourth rake, may deposit the gavel.

On the Pacific coast of America the wheat farms are of immense size, sometimes as large as 20,000 acres in a single field, and the climate is very dry, so that the grain is allowed to ripen in the field. These conditions have enabled American farmers to make use of headers and combined heading and threshing machines.

FIG. 41.—Header.

The header frame is mounted upon two wheels and has a pole extending to the rear, at the end of which is a swivelled steering wheel operated by a suitable tiller (Fig. 41). An evener is pivoted forward of the steering wheel, and to this the horses are attached and push the machine in advance. At the forward end of the frame a platform is hinged and can be adjusted vertically by means of a long lever extending back to the driver. This platform carries the cutting apparatus and the platform apron, which delivers at one side to an elevator. The cutting apparatus is adjusted to cut the heads from the grain, leaving the straw, and the heads are discharged into a wagon which moves along with the header. The header cuts a much wider swathe than the self-binder, and therefore, under the conditions to which it is adapted, is capable of doing more work.

The next step in decreasing the cost of harvesting was to combine with the header a threshing machine, the former being attached to the side of the latter, and delivering the grain thereto. The grain is then threshed out and bagged at the rate of 25 to 45 acres per day, according to the stand of grain and other varying conditions, thus reducing the cost

FIG. 40.—Sweep-rake reaper.

sleeved in the other, and having an independent movement in opening and closing the jaws to receive the loop.

from 6 to 9 cents per 100 pounds below that incurred when a header alone is used.

By applying a traction engine to a combined harvester, it is possible to increase the width of cut and thus add still further to its capacity. The machine shown in Fig. 42 is built with a cut as great as 42 feet, and will cut, thresh, reclean and sack 125 acres of wheat in one

day, requiring eight men to operate it. It is undoubtedly the most economical machine in use for harvesting grain.

Fig. 43 illustrates a harvesting outfit consisting of engine, thresher, header, water-tank waggon, and cook-house, travelling from ranch to ranch, which gives a good idea of the scale on which this work is done.

FIG. 42.—Combined steam harvester.

FIG. 43.—Combined harvesting outfit.

Corn Harvesters.

Until very recently, corn (maize) was harvested in America by hand, sometimes by breaking off the ears and leaving the stalks standing, and turning the cattle in to feed, and sometimes by cutting the stalks with a

corn knife and securing them in shocks. Within the last few years machines have been built for performing this very laborious work. If the intention be to leave the stalks standing, a machine called a stripper and husker is used, which passes the stalks between two inclined rollers

as the machine advances, the ears being snapped from the stalks by the rollers and falling on to a travelling carrier by which they are fed into a husker, and from thence to a waggon travelling with the machine. If the corn is to be shocked, a machine of the type shown in Fig. 44 is employed.

FIG. 44.—Corn harvester and binder.

corn knife and securing them in shocks. Within the last few years machines have been built for performing this very laborious work. If the intention be to leave the stalks standing, a machine called a stripper and husker is used, which passes the stalks between two inclined rollers

In this type of corn harvester a pair of inclined gatherers passes, one on each side of the row, picking up all down stalks, and feeding them through the machine by means of the gathering chains which support them as they are cut off by the knife. The stalks are then pushed to the rear by the packers of a vertically placed automatic binder, operating in the same way as a grain binder, to bind the bundle securely and discharge it into the bundle carrier, which retains it until enough is accumulated to form a shock. The bundle carrier is then operated and deposits the bundles on the ground.

Another type of corn harvester cuts the stalks in a vertical position, as above described, but forces them over on to an inclined table, down which they slide into a horizontal binder, where they are bound in the same way as in a grain binder.

The corn having been shocked, it is now customary to feed the stalks to a husking and shredding machine, in which the ears are snapped by rollers from the stalks, and then pass on to a cylinder having a series of knives, which split the stalk and tear it into small pieces. It is finally

discharged by an elevator and hauled away to be used in feeding stock. The ears of corn snapped off fall between a pair of husking rolls, which strip off the husks, the latter being carried off with the shredded stalks.

The ears of corn are then fed to a corn sheller, which rolls and rubs them between toothed disks until the kernels are detached, and they are then passed through cleaning devices in order to separate them from the chaff.

In Fig. 45 is shown a threshing machine for separating wheat and other small grain from their straw. The grain is fed between a rotating toothed cylinder and a toothed concave, by which means the straw is thoroughly beaten and the grain shaken from its husk. The straw then passes over shaking screens which shake down the grain, the latter being thoroughly cleaned by a blast of air passing upward through the screens. The straw is finally blown out through the stacking pipe on to the stack.

In conclusion, it may be said that the improvements in

agricultural machinery in the last few years have made possible the opening up of vast tracts of the world's farming lands which would otherwise have remained

FIG. 45.—Threshing machine.

unproductive for years to come, on account of the scarcity of labour, and have enabled agricultural operations to be carried out upon such a scale as greatly to reduce the cost of food to all the world. (F. C. S.)

GENERAL SURVEY, 1875-1900.

THE time which has elapsed since the article AGRICULTURE was published in the ninth edition of the *Encyclopædia Britannica* has been a fateful period for the greatest British industry. The hopeful views that were expressed at the conclusion of that article have not been realized. The great future that seemed then to await the application of steam power to the tillage of the soil has proved illusory. The clay soils of England, the latent fertility of which was to be brought into play in a fashion that should mightily augment the home-grown supplies of food, remain almost as intractable as ever, and the extent of land devoted to the cultivation of corn crops, instead of expanding, has diminished in a degree to which there is no

recorded parallel. Farmers of long experience commonly look back to 1874 as the last of the really good years, and consider that the palmy days of British agriculture began to dwindle at about that time. The shadow of the approaching depression had already fallen upon the land before the year 1875 had run its course, and the outlook became ominous as the decade of the 'seventies neared its close. One memorable feature was associated with 1877 in that this was the last year in which the dreaded cattle plague (rinderpest) made its appearance in England. There has been no record of it in the British isles since that year, and it is hoped that it has been banished for ever. The same year, 1877, was the last also in which the annual average price of English wheat exceeded 50s. per imperial quarter. The average was 56s. 9d. that year, but it has never since been within 10s. of this level. With declining prices for farm produce came that year of unhappy memory, 1879, when persistent rains and an almost sunless summer ruined the crops, and reduced many farmers to a state of destitution. Much of the grain was never

¹ These portraits are not intended to convey any idea of the relative sizes of the different animals. In plate 14, for example, the Hampshire Down Ram, though represented by a smaller picture, is a decidedly bigger animal than the Southdown Ram portrayed in the same plate.

harvested, whilst owing mainly to the excessive floods there commenced an outbreak of liver-rot in sheep, due to the ravages of the fluke parasite. This continued for several years, and the mortality was so great that its adverse effects upon the ovine population of the country were still perceptible ten years afterwards. A fall in rents was the necessary sequel of the agricultural distress, to inquire into which a royal commission

*Royal
commission,
1879.*

was appointed in 1879, under the chairmanship of the duke of Richmond and Gordon. Its report, published in 1882, testified to "the great extent and intensity of the distress which has fallen upon the agricultural community. Owners and occupiers have alike suffered from it. No description of estate or tenure has been exempted. The owner in fee and the life tenant, the occupier, whether of large or of small holding, whether under lease, or custom, or agreement, or the provisions of the Agricultural Holdings Act—all without distinction have been involved in a general calamity." The two most prominent causes assigned for the depression were bad seasons and foreign competition, aggravated by the increased cost of production and the heavy losses of live stock. Abundant evidence was forthcoming as to the extent to which agriculture had been injuriously affected "by an unprecedented succession of bad seasons." As regards the pressure of foreign competition, it was stated to be greatly in excess of the anticipations of the supporters, and of the apprehensions of the opponents, of the repeal of the Corn Laws. Whereas formerly the farmer was to some extent compensated by a higher price for a smaller yield, in recent years he had had to compete with an unusually large supply at greatly reduced prices. On the other hand, he had enjoyed the advantage of an extended supply of feeding-stuffs—such as maize, linseed cake, and cotton cake—and of artificial manures, imported from abroad. The low price of agricultural produce, beneficial though it might be to the general community, had lessened the ability of the land to bear the proportion of taxation which had heretofore been imposed upon it. The legislative outcome of the findings of this royal commission was the Agricultural Holdings Act 1883, a measure which continued in force in its entirety till 1901, when a new Act came into operation.

The apparently hopeless outlook for corn-growing compelled farmers to cast about for some other means of subsistence, and to rely more than they had hitherto done upon the possibilities of stock-breeding. It was in particular the misfortunes of the later 'seventies that gave the needed fillip to that branch of stock-farming concerned with the production of milk, butter, and cheese, and from this period may be said to date the revival of the dairying industry, which received a powerful impetus through the introduction of the centrifugal cream separator, and was fostered by the newly-established British Dairy Farmers' Association. The generally wet character of the seasons in 1879 and the two or three years following was mainly responsible for the high prices of meat, so that the supplies of fresh beef and mutton from Australia which now began to arrive found a ready market, and the trade in imported fresh meat which was thus commenced has practically continued to expand ever since. The great losses arising from spoilt hay crops served to stimulate experimental inquiry into the method of preserving green fodder known as ensilage, with the result that the system eventually became successfully incorporated in the ordinary routine of agricultural practice. A contemporaneous effort in the direction of drying hay by artificial means led to nothing of practical importance. By 1882 the cry as to land going out of cultivation became loud and general, and the migration of the rural population into the

towns in search of work continued unchecked. In 1883 foot-and-mouth disease was terribly rampant amongst the herds and flocks of Great Britain, and was far more prevalent than it has ever been since. It was about this time that the first experiments were made (in Germany) with basic slag, a material which had hitherto been regarded as a worthless by-product of steel manufacture. A year or two later field trials were begun in England, with the final result that basic slag has become recognized as a valuable source of phosphorus for growing crops, and is now in constant demand for application to the soil as a fertilizer. In 1883 the veterinary department of the Privy Council—which had been constituted in 1865 when the country was ravaged by cattle plague—was abolished by order in council, and the "Agricultural Department" was substituted, but no alteration was effected in the work of the department, so far as it related to animals. In 1889 the Board of Agriculture (for Great Britain) was formed under an Act of parliament of that year (52 & 53 Vict. c. 30), and the immediate control of the Agricultural Department was transferred from the clerk of the Privy Council to the secretary of the Board of Agriculture, where it remains. A Minister for Agriculture had for years been asked for in the interests of the agricultural community, and the functions of this office are discharged by the president of the Board of Agriculture, whose appointment of course is, like that of the president of the Board of Trade, a political one, and may or may not carry with it a seat in the Cabinet. The Board of Agriculture, on its establishment, took over from the Privy Council the responsibilities of the Contagious Diseases (Animals) Acts, besides the comprehensive duties of the Land Commission, and the authority and responsibilities of the Commissioners of Her Majesty's Works and Public Buildings under the Survey Act of 1870. The Board is entrusted with the collection and preparation of statistics relating to agriculture and forestry, the inspection of schools (not being public elementary schools) in which technical instruction is given in agriculture or forestry, and the instituting of such experimental investigations as may be deemed conducive to the progress of agriculture and forestry. The election took place in the same year (1889) of the first county councils, and the allotment to them of various sums of money under the Local Taxation (Customs and Excise) Act 1890 enabled local provision to be made for the promotion of technical instruction in agriculture. It was at about this time that the value of a mixture of lime and sulphate of copper (*bouillie bordelaise*), sprayed in solution upon the growing plants, came to be recognized as a check upon the ravages of potato disease.

*Board of
Agriculture,
1889.*

The general experience of the decade of the 'eighties was that of disappointing summers, harsh winters, falling prices, declining rents, and the shrinkage of land values. It is true that one season of the series, that of 1887, was hot and droughty, but the following summer was exceedingly wet. Nevertheless the decade closed more hopefully than it opened, and found farmers taking a keener interest in grass land, in live stock, and in dairying. Cattle-breeders did well in 1889, but sheep-breeders fared better; on the other hand, owing to receding prices, corn-growers were more disheartened than ever. With the incoming of the last decade of the century there seemed to be some justifiable hopes of the dawn of better times, but they were speedily doomed to disappointment. In 1891 excessively heavy autumn rains washed the arable soils to such an extent that the next season's corn crops were below average. Wheat in particular was a poor crop in 1892, and the low yield was associated with falling prices, due to large imports. The hay crop was very inferior, and in

some cases it was practically ruined. This gave a stimulus to the trade in imported hay, which rose from 61,237 tons in 1892 to 263,050 tons in 1893, and despite some large home-grown crops in certain subsequent years (1897 and 1898) this expansion has never since been wholly lost. The misfortunes of 1892 proved to be merely a preparation for the disasters of 1893, in which year occurred the most destructive drought within living memory. Its worst effects were seen upon the light land farms of England, and so deplorable was the position that a Royal

*Royal
Commis-
sion, 1893.*

Commission on agricultural depression was appointed in September of that year under the chairmanship of Mr Shaw Lefevre. Thus, within the last quarter of the 19th century—and, as a matter of fact, only fourteen years apart—two Royal Commissions on agriculture were appointed, the one in a year of memorable flood, 1879, and the other in a year of disastrous drought, 1893. The report of the Commission of 1893 was issued in March 1896. Amongst its chief recommendations were those relating to amendments in the Agricultural Holdings Acts, and to tithe rent-charge, railway rates, damage by game, sale of adulterated products, and sale of imported goods (meat, for example) as home produce. Two legislative enactments arose out of the work of this Commission. In the majority report it was stated “that, in order to place agricultural lands in their right position as compared with other ratable properties, it is essential that they should be assessed to all local rates in a reduced proportion of their ratable value.” The Agricultural Rates Act, 1896, gave effect to this recommendation. Its objects were to relieve agricultural land from half the local rates, and to provide the means of making good out of Imperial funds the deficiency in local taxation thereby caused. It was provided that the Act should continue in force only till 31st March 1902, but a further Act in 1901 extended the period by four years. Meanwhile the Royal Commission on local taxation was inquiring into the general incidence of local taxation, both urban and rural, and its proper adjustment between real and personal property, and presented its report in the summer of 1901. The other measure arising out of the report of the Royal Commission of 1893 was the Agricultural Holdings Act, 1900. This is an amending Act and not a consolidating Act; consequently it has to be read as if incorporated into the already existing Acts. As affecting agricultural practice there are three noteworthy improvements in respect of the making of which, without the consent of or notice to his landlord, a tenant may claim compensation—(1) the consumption on the holding “by horses, other than those regularly employed on the holding,” of corn, cake, or other feeding-stuff not produced on the holding; (2) the “consumption on the holding by cattle, sheep, or pigs, or by horses other than those regularly employed on the holding, of corn proved by satisfactory evidence to have been produced and consumed on the holding”; (3) “laying down temporary pasture with clover, grass, lucerne, sainfoin, or other seeds sown more than two years prior to the determination of the tenancy.”

After 1894, in which year the brilliant prospects of a bountiful harvest were ultimately extinguished by untimely and heavy rains, all the remaining seasons of the closing decade of the 19th century were dominated by drought. A fact that was amply illustrated, moreover, is that the period of incidence of a drought is not less important than its duration, and the same is true of abnormal rainfall. A spring drought, a summer drought, an autumn drought, each has its distinctive characteristics in so far as the effect upon the crops is concerned. The hot drought of 1893 extended over the spring and summer months, but there was an abun-

dant rainfall in the autumn; correspondingly there was an unprecedentedly bad yield of corn and hay crops, but a moderately fair yield of the main root crops (turnips and swedes). In 1899 the drought became most intense in the autumn, after the corn crops had been harvested, but during the chief period of growth of the root crops; correspondingly the corn crops of that year rank very well amongst the crops of the decade, but the yield of turnips and swedes was the worst on record. It is quite possible for a hot dry season to be associated with a large yield of corn, provided the drought is confined to a suitable period, as was the case in 1896, and still more so in 1898; the English wheat crops in those years were probably the biggest in yield per acre that had been harvested since 1868, which is always looked back upon as a remarkable year for wheat. The drought of 1898 was interrupted by copious rains in June, and these falling on a warm soil led to a rapid growth of grass and, as measured by yield per acre, an exceedingly heavy crop of hay.

With the exceptions of 1891 and 1894, every year in the period 1891-1900 was stricken by drought. The two meteorological events of the decade which will probably live longest in the recollection were, however, the terrible drought of 1893, resulting in a fodder famine in the succeeding winter, and the severe frost of ten weeks' duration at the beginning of 1895. Between these two occurrences came the disastrous decline in the value of grain in the autumn of 1894, when the weekly average price of English wheat fell to the record *minimum* of 17s. 6d. per imperial quarter. As a consequence, the extent of land devoted to wheat in the British isles receded in 1895 to less than 1½ million acres, which is the lowest area on record. Successful trials of sulphate of copper solution as a means of destroying charlock in corn crops took place in the years 1898-1900. Charlock is a most persistent cruciferous weed, but if sprayed when young with the solution named it is killed, the corn plants being uninjured.

Amongst recent legislative measures of importance to agriculturists mention should be made, in addition to those that have been referred to, of the Tithe Rent-charge Recovery Act, 1891, which transfers the liability for payment of tithe from the occupier to the owner. In the same year was passed the Markets and Fairs (Weighing of Cattle) Act. The object of the Small Holdings Act, 1892, was to facilitate the acquisition of small agricultural holdings. It provides that a county council may acquire any suitable land, with the object of allotting from one to fifty acres, or, if more than fifty acres, of an annual value not exceeding £50, to persons who desire to buy, and will themselves cultivate, the holdings. If, owing to proximity to a town or otherwise, the prospective value is too high, the council may hire such land for the purpose of letting it. The Fertilizers and Feeding Stuffs Act, 1893, compels sellers of fertilizers (*i.e.*, manures), manufactured or imported, to state the percentage of the nitrogen, of the soluble and insoluble phosphates, and of the potash in each article sold, and this statement is to have the effect of a warranty. Similar stringent conditions apply as regards the sale of feeding stuffs for live stock. The Finance Act of 1894, with its great changes in the death duties, overshadowed all other Acts of that year both in its immediate effects and in its far-reaching consequences. The Copyhold Consolidation Act, 1894, supersedes six previous copyhold statutes, but does not effect any alteration in the law concerning enfranchisement. The Diseases of Animals Act, 1896, provided for the compulsory slaughter of imported live stock at the place of landing. The Light Railways Act and the Locomotives on Highways Act were added to the Statute Book in 1896, and various clauses in

*Legisla-
tion.*

*Effects of
drought.*

the Finance Act effected reforms in respect of the death duties, the land-tax, farmers' income-tax, and the beer duty. The Chaff-cutting Machines (Accidents) Act, 1897, is a measure very similar in its intention to the Threshing Machines Act, 1878, and provides for the automatic prevention of accidents to persons in charge of chaff-cutting machines. The Sale of Food and Drugs Act, 1899, has special reference in its earlier sections to the trade in dairy produce and margarine. In 1899 was also passed the Act establishing a department of agriculture and technical instruction in Ireland.

THE ACREAGE OF CROPS.

The most notable feature in connexion with the cropping of the land of the United Kingdom during the last quarter of the 19th century was the lessened cultivation of the cereal crops, associated with an expansion in the area of grass land. At the beginning of the period the aggregate area under wheat, barley, and oats was nearly 10½ million acres; at the close it did not much exceed 8 million acres. There was thus a withdrawal during the period of considerably over 2 million acres from cereal cultivation. From Table I., showing the acreages at

TABLE I.—Areas of Cereal Crops in the United Kingdom—Acres.

Year.	Wheat.	Barley.	Oats.	Total.
1875	3,514,088	2,751,362	4,176,177	10,441,627
1880	3,065,895	2,695,000	4,191,716	9,952,611
1885	2,553,092	2,447,169	4,282,594	9,282,855
1890	2,483,595	2,300,994	4,137,790	8,922,379
1895	1,456,042	2,346,367	4,527,899	8,330,308
1900	1,901,014	2,172,140	4,145,633	8,218,787

intervals of five years, it will be learnt that the loss fell chiefly upon the wheat crop, which at the close of the period occupied barely more than half the area assigned to it at the beginning. If the land taken from wheat had been cropped with one or both of the other cereals, the aggregate area would have remained about the same. This, however, has not been the case, for a fairly uniform decrease in the barley area has been accompanied by somewhat irregular fluctuations in the acreage of oats. To the decline in prices of home-grown cereals the decrease in area is largely attributable. The extent of this decline is seen in Table II., wherein are given the annual average prices, calculated upon returns from the statutory markets of England and Wales (numbering 196¹ since 1890, under the Corn Returns Act, 1882). These prices are per imperial quarter,—that is, 480 lb of wheat, 400 lb of barley, and 312 lb of oats, representing 60 lb, 50 lb, and 39 lb per bushel respectively. Since 1883 the annual average price of English *wheat* has never again been so high as 40s. per quarter, and only twice since 1892 has it exceeded 30s. In one of these exceptional years, 1898, the average rose to 34s., but this was due entirely to a couple of months of inflated prices in the early half of the year, when the outbreak of war between Spain and the United States of America coincided with a huge speculative deal in the latter country. The weekly average prices of English wheat in 1898 fluctuated between 48s. 1d. and 25s. 5d. per quarter, the former being the highest weekly average since 1882. The *minimum* annual average was 22s. 10d. in 1894, in the autumn of which year the weekly average sank to 17s. 6d. per quarter, the lowest on record. Wheat was so great a glut in the market that various methods were devised for feeding it to stock, a purpose for which it is not specially suited; in thus utilizing the grain, however, a smaller loss was often incurred than in sending it to market. In 1894 the monthly average price for October, the chief month for wheat-sowing in England, was only 17s. 8d. per

¹ Altered to 190 on 1st January 1901.

quarter, and farmers naturally shrank from seeding the land freely with a crop which could not be grown except

TABLE II.—Gazette Annual Average Prices per Imperial Quarter of British Cereals in England and Wales, 1875 to 1900.

1899	25	8	25	7	17	0
1900	26	11	24	11	17	7

at a heavy loss. The result was that in the following year the wheat crop of the United Kingdom was harvested upon the smallest area on record,—less than 1½ million acres. In only one year of the last quarter-century, 1878, did the annual average price of English *barley* touch 40s. per quarter; it has never again reached 30s. since 1885, whilst in 1895 it fell to so low a level as 21s. 11d. The same story of declining prices applies to *oats*. An average of 20s. per quarter was touched in 1891, but with that exception this useful feeding grain has not reached that figure since 1885. In 1895 the average price of 480 lb of wheat, at 23s. 1d., was identical with that of 312 lb of oats in 1880, and it was less in the preceding year. The declining prices that have operated against the growers of wheat should be studied in conjunction with Table III., which shows, at intervals

TABLE III.—Imports into the United Kingdom of Wheat Grain, and of Wheat Meal and Flour—Cwt.

Year.	Wheat Grain.	Meal and Flour.	Total.
1875	51,876,517	6,136,083	58,012,600
1880	55,261,924	10,558,312	65,820,236
1885	61,498,864	15,832,843	77,331,707
1890	60,474,180	15,773,336	76,247,516
1895	81,749,955	18,368,410	100,118,365
1900	68,615,990	21,642,035	90,158,025

of five years, the imports of wheat grain and of wheat meal and flour into the United Kingdom. The import of the manufactured product is increasing at a much greater ratio than that of the raw grain, for whilst in 1875 the former represented less than one-ninth of the total, by 1900 the proportion had risen to nearly one-fourth. The offal, which is quite as valuable as the flour itself, is thus retained abroad instead of being utilized for stock-feeding purposes in the United Kingdom. The highest and lowest areas of wheat, barley, and oats in the United Kingdom during the period 1875-1900 were the following:—

Wheat . . .	3,514,088 acres in 1875	1,456,042 acres in 1895
Barley . . .	2,931,809 acres in 1879	2,068,760 acres in 1898
Oats . . .	4,527,899 acres in 1895	3,998,200 acres in 1879

These show differences amounting to 2,058,046 acres for wheat, 863,049 acres for barley, and 529,699 acres for oats. The acreage of wheat, therefore, has fluctuated the most, and that of oats the least. Going back to 1869, it is found that the extent of wheat in that year was 3,981,989 acres, or very little short of four million acres.

The acreage of *rye* grown in the United Kingdom as a grain crop is small, the respective *maximum* and *minimum* areas during the period 1875-1900 having been 102,676 acres in 1894 and 47,937 acres in 1880. Rye is perhaps more largely grown as a green crop to be fed off by sheep, or cut green for soiling, in the spring months.

Of corn crops other than cereals, *beans* and *peas* are both less cultivated than formerly. In the period 1875-1900 the area of beans in the United Kingdom fluctuated between 574,414 acres in 1875 and 230,429 acres in 1897, and that of peas between 318,410 acres in 1875 and 163,325 acres in 1899. The area of peas has thus shrunk nearly one-half, and that of beans more than one-half. Taking cereals and pulse corn together, the aggregate areas of wheat, barley, oats, rye, beans, and peas in the United Kingdom have varied as follows over the five quinquennial intervals embraced in the period 1875-1900:—

Year.	Acrea.	Year.	Acrea.
1875	11,399,030	1890	9,574,249
1880	10,872,086	1895	8,865,338
1885	10,014,625	1900	8,707,602

Disregarding minor fluctuations, there has thus been a loss of corn land over the quarter-century of 2,691,639 acres, or nearly 24 per cent.

The area that has been withdrawn from corn growing is not to be found under the head of what are termed "green crops." In 1900 the total area of these crops in the United Kingdom was 4,301,774 acres, made up thus:—

Crop.	Acrea.
Potatoes	1,227,569
Turnips and swedes	1,994,421
Mangel	484,050
Cabbage, kohl-rabi, and rape	242,967
Vetches or tares	181,679
Other green crops	171,088

The extreme aggregate areas of these crops during the quarter-century were 5,057,029 acres in 1875 and 4,261,441 acres in 1898. At five-year intervals the areas have been:—

Year.	Acrea.	Year.	Acrea.
1875	5,057,029	1890	4,534,145
1880	4,746,293	1895	4,399,949
1885	4,765,195	1900	4,301,774

These crops, therefore, which, except potatoes, are used mainly for stock-feeding, have like the corn crops been grown on gradually diminishing areas.

The land that has been lost to the plough is found to be still further augmented when an inquiry is instituted into the area devoted to clover, sainfoin, and grasses under rotation. In the period 1875-1900 this area has fluctuated between 6,557,748 acres in 1878 and 5,862,754 acres in 1894, whilst the areas at five-year intervals are given in Table IV. Under the old Norfolk or four-course rotation (roots, barley, clover, wheat) land thus seeded with clover or grass seeds was intended to be ploughed up at the end of a year. Labour difficulties, low prices of produce, bad seasons, and similar causes provided inducements for leaving the land in grass for two years, or over three years or more, before breaking it up for wheat. In many cases it would be decided to let such land remain under grass indefinitely, and thus it would no longer be enumerated in the Agricultural Returns as temporary grass land, but would pass into the category of permanent grass land, or what is often spoken of as "permanent pasture." Whilst much grass land has been laid down with the intention

from the outset that it should be permanent, at the same time some considerable areas have through stress of circumstances been allowed to drift from the temporary or rotation grass area to the permanent list, and have thus still further diminished the area formerly under the dominion of the plough. The column relating to permanent grass in Table IV. shows clearly enough how the British Isles have

TABLE IV.—Areas of Grass Land (excluding Heath and Mountain Land) in the United Kingdom—Acres.

Year.	Temporary (i.e. not broken up under rotation).	Permanent (i.e. in rotation).	Total.
1875	6,337,953	23,772,602	30,110,555
1880	6,389,232	24,717,092	31,106,324
1885	6,738,206	25,616,071	32,354,277
1890	6,097,210	27,115,425	33,212,635
1895	6,061,139	27,831,117	33,892,256
1900	6,024,317	28,261,529	34,285,846

for the last quarter-century been becoming more pastoral, whilst figures previously quoted demonstrate the extent to which they have become less arable. In the period 1875-1900 the extreme areas returned as "permanent pasture"—a term which, it should be clearly understood, does not include heath or mountain land, of which there are in Great Britain alone about thirteen million acres used for grazing—were 23,772,602 acres in 1875, and 28,261,529 acres in 1900, whilst the totals at five-year intervals are stated in Table IV. Comparing 1900 with 1875 the increase in permanent grass land is found to amount to close upon $4\frac{1}{2}$ million acres, or about 19 per cent.

On account of the greater humidity and mildness of its climate Ireland is more essentially a pastoral country than Great Britain. The distribution between the two islands of such important crops of arable land as cereals and potatoes is indicated in Table V. The figures are those

TABLE V.—Areas of Cereal and Potato Crops in Great Britain and Ireland in 1900.

	Wheat.		Barley.	
	Acrea.	Per Cent.	Acrea.	Per Cent.
Great Britain	1,845,042	97·2	1,990,265	92
Ireland	53,797	2·8	174,006	8
Total	1,898,839	100·0	2,164,271	100
	Oats.		Potatoes.	
	Acrea.	Per Cent.	Acrea.	Per Cent.
Great Britain	3,026,088	73·3	561,361	46
Ireland	1,104,848	26·7	654,413	54
Total	4,130,936	100·0	1,215,774	100

for 1900, but, though the absolute acreages vary somewhat from year to year, there is not much variation in the percentages. The comparative insignificance of Ireland in the case of the wheat and barley crops, represented by 2·8 and 8 per cent. respectively, receives some compensation when oats and potatoes are considered, fully one-fourth of the area of the former and more than half that of the latter being claimed by Ireland. It is noteworthy, however, that Ireland is year by year placing less reliance upon the potato crop. In 1888 the area of potatoes in Ireland was 804,566 acres, but it continuously contracted each year, until in 1900 it did not exceed 654,413 acres, or 150,153 acres less than twelve years previously.

A similar comparison for the several sections of Great Britain, as instituted in Table VI., shows that to England belongs about 95 per cent. of the wheat area, over 80 per cent. of the barley area, over 60 per cent. of the oats area, and 70 per cent. of the potato area, and these proportions do not vary much from year to year. The figures for

cereals are important, as they indicate that it is the farmers of England who are the chief sufferers through the diminishing prices of corn; and particularly is this true of East Anglia, where corn-growing is more largely pursued than in any other part of the country. Scotland

TABLE VI.—*Areas of Cereal and Potato Crops in England, Wales, and Scotland, and in Great Britain, in 1900.*

	Wheat.		Barley.	
	Acres.	Per Cent.	Acres.	Per Cent.
England . . .	1,744,556	94·6	1,645,022	82·7
Wales . . .	51,654	2·8	105,048	5·3
Scotland . . .	48,832	2·6	240,195	12·0
Great Britain . .	1,845,042	100·0	1,990,265	100·0
	Oats.		Potatoes.	
	Acres.	Per Cent.	Acres.	Per Cent.
England . . .	1,860,513	61·5	396,936	70·7
Wales . . .	216,447	7·1	33,225	5·9
Scotland . . .	949,128	31·4	131,200	23·4
Great Britain . .	3,026,088	100·0	561,361	100·0

possesses nearly one-third of the area of oats and nearly one-fourth of that of potatoes. Beans are almost entirely confined to England, and this is even more the case with peas. The mangel crop also is mainly English, the summer in most parts of Scotland being neither long enough nor warm enough to bring it to maturity.

THE PRODUCE OF CROPS.

Whilst the returns relating to the acreage of crops and the number of live stock in Great Britain have been officially collected in each year since 1866, the annual official estimates of the produce of the crops in the several sections of the kingdom do not extend back beyond 1885. The practice is for the Board of Agriculture to appoint local estimators, who report in the autumn as to the total production of the crops in the localities respectively assigned to them. By dividing the total production, say of wheat, in each county by the number of acres of wheat as returned by the occupiers at 4th June, the estimated average yield per acre is obtained. It is important to notice that the figures relating to total production and yield per acre are only *estimates*, and it is not claimed for them that they are anything more. The fact that much of the wheat to which the figures apply is still in the stack after the publication of the figures shows that the latter are essentially estimates. The total produce of any crop in a given year must depend mainly upon the acreage grown, whilst the average yield per acre will be determined chiefly by the character of the season. In Table VII. are

TABLE VII.—*Estimated Annual Total Produce of Corn Crops in the United Kingdom, 1890 to 1900—Thousands of Bushels.*

Year.	Wheat.	Barley.	Oats.	Beans.	Peas.
1890	75,994	80,794	171,295	11,860	6313
1891	74,743	79,555	166,472	10,694	5777
1892	60,775	76,939	168,181	7,054	5028
1893	50,913	65,746	168,588	4,863	4756
1894	60,704	73,601	190,863	7,198	6229
1895	38,285	75,028	174,476	5,626	4732
1896	58,247	77,825	162,860	6,491	4979
1897	56,296	72,613	163,556	6,650	5250
1898	74,885	74,731	172,578	7,267	4858
1899	67,261	74,532	166,140	7,566	4431
1900	54,322	68,546	165,137	7,469	4072

shown, in thousands of bushels, the estimated produce of the corn crops of the United Kingdom in each of the years 1890 to 1900. The largest area of wheat in the period was that of 1890, and the smallest was that of 1895;

the same two years are seen to have been respectively those of highest and lowest total produce. It is noteworthy that in 1895 the country produced little more than half as much wheat as in any one of the years 1890, 1891, and 1898. The produce of barley, like that of oats, is less irregular than that of wheat, the extremes for barley being 80,794,000 bushels and 65,746,000 bushels, and those for oats, 190,863,000 bushels and 162,860,000 bushels. As to beans, the produce of 1890 was about equal to that of 1892 and 1893 together. Similar details for potatoes, roots, and hay, brought together in Table VIII.,

TABLE VIII.—*Estimated Annual Total Produce of Potatoes, Roots, and Hay in the United Kingdom, 1890 to 1900—Thousands of Tons.*

Year.	Potatoes.	Turnips.	Mangels.	Hay.

show that the production of potatoes varies much from year to year. The imports of potatoes into the United Kingdom vary, to some extent, inversely; thus, the low production in 1897 was accompanied by an increase of imports from 3,921,205 cwt. in 1897 to 6,751,728 cwt. in 1898. No very great reliance can be placed upon the figures relating to turnips (which include swedes), as these are mostly fed to sheep on the ground, so that the estimates as to yield are necessarily vague. Mangels are probably more closely estimated, as these valuable roots are carted and stored for subsequent use for feeding stock. Under hay are included the produce of clover, sainfoin, and rotation grasses, and also that of permanent meadow. The extent to which the annual production of the leading fodder crop may vary is shown in the table by the two consecutive years 1893 and 1894; from only nine million tons in the former year the production rose to upwards of fifteen million tons in the latter, an increase of fully 70 per cent.

Turning to the average yields per acre, as ascertained by dividing the number of acres into the total produce, the results of a decade are collected in Table IX. The effects of a prolonged spring and summer drought, like that of 1893, are exemplified in the circumstance that four corn crops and the two hay crops all register their *minimum* average yields that year. On the other hand, the season of 1898 was exceptionally favourable to cereals and to hay. The effects of a prolonged autumn drought, as distinguished from spring and summer drought, are shown in the very low yield of turnips in 1899. Mangels are sown earlier and have a longer period of growth than turnips; if they become well established in the summer they are less susceptible to autumn drought. The hay made from clover, sainfoin, and grasses under rotation generally gives a bigger average yield than that from permanent grassland. The mean values at the foot of the table—they are not, strictly speaking, exact averages—indicate the average yields per acre in the United Kingdom to be about 30 bushels of wheat, 34 bushels of barley, 40 bushels of oats, 27 bushels of beans, 26 bushels of peas, 4½ tons of potatoes, 13 tons of turnips and swedes, 17 tons of mangels, 31 cwt. of hay from temporary grass, and 28 cwt. of hay from permanent grass. Although enormous

single crops of mangels are sometimes grown, amounting occasionally to 100 tons per acre, the general average yield of 17 tons is about 4 tons more than that of turnips and swedes. Again, although from the richest old permanent meadow lands very heavy crops of hay are taken season after season, the general average yield of permanent grass is about 3 cwt. of hay per acre less than that from clover, sainfoin, and grasses under rotation. The general average yields of the corn crops are not fairly comparable one with the other because they are given by

measure and not by weight, whereas the weight per bushel varies considerably. For purposes of comparison it would be much better if the yields of corn crops were estimated in cwt. per acre. This, indeed, is the practice in Ireland, and in order to incorporate the Irish figures with those for Great Britain so as to obtain average values for the United Kingdom, the Irish yields are calculated into bushels at the rate of 60 lb to the bushel of wheat, of beans, and of peas, 50 lb to the bushel of barley, and 39 lb to the bushel of oats.

The figure denoting the general average yield per acre of any class of crop needs readjusting after every successive harvest. If a decennial period be taken, then—for the purpose of the new calculation—the earliest year is omitted and the latest year added, the number of years continuing at ten. Adopting this course in the case of the cereal crops of Great Britain the decennial averages recorded in Table X. are obtained, the period 1885-94

TABLE X.—*Decennial Average Yields in Great Britain of Wheat, Barley, and Oats—Bushels per acre.*

10-Year Periods.	Wheat.	Barley.	Oats.
1885-1894	29·32	33·02	38·21
1886-1895	28·81	32·68	38·23
1887-1896	29·49	32·82	38·13
1888-1897	29·19	32·97	38·51
1889-1898	29·86	33·26	38·86
1890-1899	30·15	33·50	38·81

being the earliest decade for which the official figures are available. It thus appears that the average yield of wheat in Great Britain, as calculated upon the crops harvested during the ten years of the 'nineties (1890-99), exceeded 30 bushels to the acre, whereas shortly before, as for the ten years ended 1895, it fell below 29 bushels. A large expansion in the acreage of the wheat crop would probably be attended by a decline in the average yield per acre, for when a crop is shrinking in area the tendency is to withdraw from it first the land least suited to its growth. The general average for the United Kingdom might then recede to rather less than 28 bushels of 60 lb per bushel, which was for a long time the accepted average—unless, of course, improved methods of cultivating and manuring the soil were to increase its general wheat-yielding capacity.¹

LIVE STOCK.

The numbers of live stock in the United Kingdom are shown at five-yearly intervals in Table XI. Under horses

are embraced only unbroken horses and horses used solely for agriculture (including mares kept for breeding). The

TABLE XI.—*Numbers of Horses, Cattle, Sheep, and Pigs in the United Kingdom.*

Year.	Horses.	Cattle.	Sheep.	Pigs.
1875	1,819,687	10,162,787	33,491,948	3,495,167
1880	1,929,680	9,871,153	30,239,620	2,863,488
1885	1,909,200	10,868,760	30,086,200	3,686,628
1890	1,964,911	10,789,858	31,667,195	4,362,040
1895	2,112,207	10,753,314	29,774,853	4,238,870
1900	2,000,402	11,454,902	31,054,547	3,663,669

highest and lowest annual totals for the United Kingdom in the period 1875-1900 were the following:—

	Highest.	Lowest.	Difference.
Horses	2,112,207 in 1895	1,819,687 in 1875	292,520
Cattle	11,519,417 in 1892	9,731,537 in 1877	1,787,880
Sheep	33,642,808 in 1892	27,448,220 in 1882	6,194,588
Pigs	4,362,040 in 1890	2,863,488 in 1880	1,498,552

The highest total in each case is in the 'nineties. After the maximum year of 1892 cattle and sheep declined continuously for three years to the totals of 1895, the diminution being mainly the result of the memorable drought of 1893. Sheep, which numbered 32,571,018 in 1878, declined continuously to 27,448,220 in 1882—a loss of over five million head in five years. This was chiefly attributable to the ravages of the liver fluke which

8-yearly periods from 1852 to 1899, and afford evidence that the higher yield of the last sixteen years is due to the seasons:—

Average of—	Bushels (of 60 lb.) per acre.
8 years 1852-59	28½
8 " 1860-67	28½
8 " 1868-75	27½
8 " 1876-83	25½
8 " 1884-91	29½
8 " 1892-99	30
82 " 1852-88	27½
16 " 1884-99	30
48 " 1852-99	28½

The average of the first thirty-two years is thus 27½ bushels per acre, of the last sixteen years 30 bushels, and of the whole forty-eight years 28½ bushels.

¹ The higher yield of wheat in recent years appears to be largely attributable to better grain-growing seasons. The yields in the experimental wheat-field at Rothamsted—where there is no change either of land or of treatment—indicate this. The following figures show the average yields per acre of the selected plots at Rothamsted over six

began in the disastrously wet season of 1879. Pigs, being prolific breeders, fluctuate more widely in numbers than cattle or sheep, for the difference of 1,498,552 in their case represents fully one-third of the highest total, whereas the difference is less than one-seventh for horses, less than one-sixth for cattle, and less than one-fifth for sheep. The relative proportions—as distinguished from the actual numbers—in which stock are distributed over the several sections of the United Kingdom do not vary greatly from year to year. Table XII., in which the totals for the United Kingdom include those for the Channel Islands and Isle of Man, illustrates the preponderance of the sheep-breeding industry in the drier climate of Great Britain and of the cattle-breeding industry in the more humid atmosphere of Ireland. In Great Britain, for every head of cattle there are about four head of sheep, whereas in Ireland the cattle slightly outnumber the sheep. Again, whilst Great Britain possesses only

half as many cattle more than Ireland, she possesses six times as many sheep. The cattle population of England alone slightly exceeds that of Ireland, but cattle are more at home on the broad plains of England than amongst the hills and mountains of Wales and Scotland, which afford suitable habitat for sheep. Hence it happens that, whilst in England sheep are not four times as numerous as cattle, in Wales they are nearly five times as numerous, and in Scotland more than six times as many. Great Britain has twice as many pigs as Ireland, but the swine industry is mainly English and Irish, and England is seen to possess nearly six times as many pigs as Wales and Scotland together, the number in the last-named country being particularly small. One English county alone, Suffolk, maintains more pigs than the whole of Scotland.

IMPORTS OF LIVE ANIMALS AND MEAT.

The stock-breeders and graziers of the United Kingdom have, equally with the corn growers, to face the brunt of foreign competition, the aggregate importation, free of

duty, of meat in the carcase and on the hoof continuing steadily to increase. Up to 1896 store cattle were admitted

¹ Including Channel Islands and Isle of Man.

into the United Kingdom for the purpose of being fattened, but under the Diseases of Animals Act of that year animals imported since then have to be slaughtered at the place of landing. The dimensions of this trade are shown in Table XIII.

The animals come mainly from the United States of America, Canada, and Argentina, and the traffic in cattle is more uniform than that in sheep, whilst that in pigs seems to have reached extinction. The quantities of dead meat imported have increased with great rapidity, a circumstance largely due to the rise of the trade in chilled and frozen meat. Fresh beef in this form is imported chiefly from the United States and Australasia, fresh mutton from Australasia and Argentina.

Table XIV. shows how rapidly this trade expanded during the decade of the 'nineties. The column headed bacon and hams indicates clearly enough that the imports of fresh meat did not displace those of preserved pig meat, for the latter expanded from 4,715,000 cwt. to 7,784,000 cwt. during the decade. The column for all dead meat includes not only the items tabulated, but also

TABLE XIV.—Quantities of Dead Meat imported into the United Kingdom, 1891-1900—Thousands of Cwt.

1900	4128	3393	695	7444	17,912

the following, the quantities stated being those for 1900:—Beef salted, 194,668 cwt.; beef, otherwise preserved, 516,529 cwt.; preserved mutton, 64,452 cwt.; salted pork, 248,710 cwt.; dead rabbits, 473,167 cwt.; meat, unenumerated, 754,114 cwt. The quantities of these are relatively small, and, excepting rabbits from Australia, they show no general tendency to increase. The extent to which these growing imports have been associated with a decline in value is shown in Table XV.

The trend of the import trade in meat, live and dead, may be gathered from Table XVI., in which are given the annual average imports for the seven quinquennial periods embraced between 1866 and 1900. An increase in live cattle has accompanied a decrease in live sheep and pigs, but the imports of dead meat have expanded nearly fourteen-fold over the period.

The rate at which the trade in imported frozen mutton is increasing as compared with the industry in

home-grown mutton is illustrated in the figures published annually by Messrs W. Weddel & Company, from which those for 1885 and for each year from 1890 to 1900 are

TABLE XVI.—Average Annual Imports of Cattle, Sheep, and Pigs, and of Dead Meat, into the United Kingdom over seven 5-yearly Periods.

Period.	Cattle.	Sheep.	Pigs.	Dead Meat.
	No.	No.	No.	Cwt.
1866-70	194,947	610,300	64,827	1,155,867

1893	340	100	1899	339	187
1894	322	128	1900	332	179

dead weight of the sheep imported on the hoof for slaughter. The home production of mutton would appear to have reached its limit, for the quantity entered under this head for 1899 is seen to be no more than that for 1890. On the other hand, the quantity imported in 1899 is double that in 1890, and quadruple that in 1885. Moreover, in 1885 the imported product was only about one-seventh as much as the home-grown, whereas in 1890

it was more than one-fourth, and in 1897 and each year since more than one-half. This large-import trade in fresh meat, which sprang up entirely within the last quarter of the 19th century, has placed an abundance of

cheap and wholesome food well within the reach of the great industrial populations of the United Kingdom. At the same time it cannot be gainsaid that it has opened the way to fraud, when butchers have palmed off upon their customers imported fresh meat as home-grown, and secured a dishonest profit by charging for it the prices of the latter, which are considerably in excess of those of the imported product. How wide is the margin for obtaining a fraudulent profit in this way is shown by the prices of home-grown and imported meat in Table XVIII. taken from the Agricultural Returns.

Many suggestions have been made to render it an offence at law for a seller to offer imported fresh meat as home-grown, but up to 1901 no legislative effect had been given to these proposals.

SALE OF CATTLE BY LIVE WEIGHT.

In connexion with the internal live stock trade of Great Britain attention must be directed to the Markets and Fairs (Weighing of Cattle) Act, 1891. The object of this measure is to replace the old-fashioned system of guessing at the weight of an animal by the sounder method of obtaining the exact weight by means of the weighbridge. The grazier buys and sells cattle much less frequently than the butcher buys them, so that the latter is naturally more skilled in estimating the weight of a beast through the use of the eye and the hand. The resort to the weighbridge should put both on an equality, but the method does not seem to have found much favour. Under the Act there are 15 scheduled places in England and 6 in Scotland, or 21 altogether (19 previous to 1898), from which returns are regularly obtained. The numbers of cattle weighed at these places in the seven years, 1893 to 1899, were respectively 92,492, 96,344, 100,033, 109,184, 111,767, 138,652, and 139,482, so that there was an increase of about 50 per cent. during the period. The numbers for Scotland are greater throughout than those for England. The scheduled places at which weighing appears to be most resorted to are Edinburgh, Aberdeen, and Glasgow in Scotland, and London, Shrewsbury, Carlisle, and Liverpool in England. But, as will be apparent from Table XIX., the

TABLE XIX.—Nos. of Cattle Weighed in Great Britain under the Markets and Fairs Weighing of Cattle Act, 1893-1900.

Year.	Entering Markets.	Weighed.	Weighed.
	No.	No.	Per Cent.
1893	1,219,208	92,492	7.59
1894	1,203,533	96,344	8.01
1895	1,186,149	100,033	8.43
1896	1,000,014	109,184	9.93
1897	1,115,133	111,767	10.02
1898	1,263,991	138,652	10.97
1899	1,236,091	139,482	11.28
1900	1,187,603	141,611	11.92

number of cattle weighed bears but an insignificant proportion to the total which pass through the scheduled markets. The figures given in Table XX. for the two years, 1898 and 1899, show how little use is made of the weighbridge in the sale of sheep and swine. Now that weighbridges are moderate in price and excellent in quality they are placed in most markets, so that there is little excuse for retaining the old empirical method of sale. As the primary object of the Act is to obtain records of prices, it follows that only in so far as statements of the prices realized, together with the description of the animals involved, are obtained is the full advantage of the statute secured. In 1899 average prices for cattle of first or prime quality ranged from 32s. 2d. per cwt. in Leeds to 38s. per cwt. in London. For second quality beasts

trate the kind of information which the Act is competent to elicit. The number of fat cattle which were reported as having been actually sold by live weight at an agreed-on price per cwt. or per stone—a most commendable innovation—was greater than ever before in 1899, and amounted to 16,844 head. The weighing of store cattle for sale is, like that of fat cattle, slowly extending.

EARLY MATURITY.

In the fattening of animals for the butcher the principle of early maturity has received full recognition. If the sole purpose for which an animal is reared is to prepare it for the block—and this is the case with steers amongst cattle and with wethers amongst sheep—the sooner it is ready for slaughter the less should be the outlay involved. During the whole time the animal is living the feeder has to pay what has been termed the "life tax"—that is, so much of the food has to go to the maintenance of the animal as a living organism, independently of that which may be undergoing conversion into what will subsequently be available in the form of beef or mutton. If a bullock can be rendered fit for the butcher at the age of two or three years, will the animal repay another year's feeding? It has been proved at the Christmas fat stock shows that the older a bullock gets the less will he gain in weight per day as a result of the feeding. With regard to this point the work of the

Smithfield shows.

Smithfield Club deserves recognition. This body was instituted in 1798 as the Smithfield Cattle and Sheep Society, the title being changed to that of the Smithfield Club in 1802. The original object—the supply of the cattle markets of Smithfield and other places with the cheapest and best meat—is still kept strictly in view. The judges, in making their awards at the show held annually in December, at (since 1862) Islington, North London, are instructed to decide according to quality of flesh, lightness of offal, age, and early maturity, with no restrictions as to feeding, and thus to promote the primary aim of the club in encouraging the selection and breeding of the best and most useful animals for the production of meat and testing their capabilities in respect of early maturity. At the first show held (at Smithfield) in 1799, two classes were provided for cattle and two for sheep, the prizes offered amounting to £52.10s. In 1839 the classes comprised seven for cattle, six for sheep, and one for pigs, with prizes to the amount of £300. By 1862 the classes had risen to 29 for cattle, 17 for sheep, and 4 for pigs, and the prize money to £2072. At the centenary show

in 1898 provision was made for 40 classes for cattle, 29 for sheep, 18 for pigs, and 7 for animals to be slaughtered, whilst to mark the importance of the occasion the prizes offered amounted to close upon £5000 in value. In 1900 there were 36 classes for cattle, 32 for sheep, 18 for pigs, and 7 for cattle and sheep to be slaughtered, and the value of the prizes was £3894. The sections provided for cattle are properly restricted to what may be termed the beef breeds; in the catalogue order they are Devon, Hereford, Shorthorn, Sussex, Red Polled, Aberdeen-Angus, Galloway, Welsh, Highland, cross-bred, and a section for Kerry, Dexter, and Shetland. It will be noticed that such characteristically milking breeds as the Ayrshire, Jersey, and Guernsey have no place here. Provision is made, however, for all the well-known breeds of sheep and swine. In the cattle classes, aged beasts of huge size and of considerably over a ton in weight used to be common, but in recent years the tendency has been to reduce the upper limit of age, and thus to bring out animals ripe for the butcher in a shorter time than was formerly the case. The latest important step in this direction was taken in 1896, when the senior class for steers, viz., animals three to four years old, was abolished, the *maximum* age at which steers were allowed to compete for prizes being reduced to three years. The cow classes were abolished in 1897, and in the schedule of the 1900 exhibition the classes for each breed of cattle were (1) for steers not exceeding two years old, (2) for steers above two years and not exceeding three years old, and (3) for heifers not exceeding three years old. The single exception is provided by the slowly-maturing Highland breed of cattle, for which classes are allotted to (1) steers not exceeding three years old, (2) steers or oxen above three years old (with no *maximum* limit), and (3) heifers not exceeding four years old. As illustrating heavy weights, there were in the 1893 show, out of 310 entries of cattle, four beasts which weighed over a ton. They were all steers of three to four years old, one being a Hereford weighing 20 cwt. 2 qr. 4 lb, and the others Shorthorns weighing respectively, 20 cwt. 2 qr., 20 cwt. 3 qr. 21 lb, and 22 cwt. 2 qr. 18 lb. In the 1895 show, out of 356 entries of cattle, there were seven beasts of more than a ton in weight. They were all three to four years old, and comprised four Shorthorns (top weight 21 cwt. 1 qr. 18 lb), one Sussex (22 cwt. 3 qr. 7 lb), and two cross-breds (top weight 20 cwt. 3 qr. 24 lb). In the 1899 show, with 311 entries of cattle, and the age limited to three years, no beast reached the weight of a ton, the heaviest animal being a cross-bred (Aberdeen-Angus and Shorthorn) which, at three years old, turned the scale at 19 cwt. 1 qr. 5 lb. Out of 259 entries of cattle at the show of 1900 the top weight was 19 cwt. 2 qr. 3 lb in the case of a Red Polled steer, aged two years and eleven months; the next being 18 cwt. 2 qr. 6 lb for a Hereford steer two years eight and a half months old. Useful figures for purposes of comparison are obtained by dividing the weight of a fat beast by the number of days in its age, the weight at birth being thrown in. The average daily gain in live weight is thus arrived at, and as the animal increases in age this average gradually diminishes, until the daily gain reaches a stage at which it does not afford any profitable return upon the food consumed. At the centenary show of the Smithfield Club in 1898 the highest average daily gains in weight amongst prize-winning cattle were provided by a Shorthorn-Aberdeen cross-bred steer (age, one year seven months; daily gain, 2.47 lb); a Shorthorn steer (age, one year seven months; daily gain, 2.44 lb); and an Aberdeen-Shorthorn cross-bred steer (age, one year ten months; daily gain, 2.33 lb). These beasts, it will be observed, were all under two years old. Amongst prize steers of two and a half to three years old, on the

same occasion, the three highest daily average gains in live weight were 2·07 lb for an Aberdeen-Angus, 1·99 lb for a Shorthorn-Aberdeen cross-bred, and 1·97 for a Sussex. In the sheep section of the Smithfield show the classes for ewes were finally abolished in 1898, and the classes restricted to wethers and wether lambs, whose function is exclusively the production of meat. At the 1900 show sheep of each breed, and also cross-breeds, competed as (1) wether lambs under twelve months old, and (2) wether sheep above twelve and under 24 months old. The only exception was in the case of the slowly-maturing Cheviot and mountain breeds, for which the second class was for wether sheep of any age above twelve months. Of prize sheep at the centenary show the largest average daily gain was 0·77 lb per head given by Oxford-Hampshire cross-bred wether lambs, aged nine months two weeks. In the case of wether sheep, twelve to twenty-four months old, the highest daily increase was 0·56 per lb per head as yielded by Lincolns, aged twenty-one months. Within the last quarter of the 19th century the stock-feeding practices of the country were much modified in accordance with these ideas of early maturity. The three-year old wethers and older oxen that used to be common in the fat stock markets are now rarely seen, excepting perhaps in the case of mountain breeds of sheep and Highland cattle. It was in 1875 that the Smithfield Club first provided competitive classes for lambs, and in 1883 the champion plate offered for the best pen of sheep of any age in the show was for the first time won by lambs, a pen of Hampshire Downs. The young classes for bullocks were established in 1880. The time-honoured notion that an animal must have completed its growth before it could be profitably fattened is no longer held, and the improved breeds which now exist rival one another as regards the early period at which they may be made ready for the butcher, by appropriate feeding and management.

In 1895 the Smithfield Club instituted a carcass competition in association with its annual show of fat stock, and it has been continued each year since. The cattle and sheep entered for this competition are shown alive on the first day, at the close of which they are slaughtered and the carcasses hung up for exhibition, with details of live and dead weights. The competition thus constitutes what is termed a "block test," and it is instructive in affording the opportunity of seeing the quality of the carcasses furnished by the several animals, and in particular the relative proportion and distribution of fat and lean meat. The live animals are judged and subsequently the carcasses, and, though the results sometimes agree, more often they do not. Tables are constructed showing the fasted live weight, the carcass weight, and the weight of the various parts that are separated from and not included with the carcass. An abundance of lean meat and a moderate amount of fat well distributed constitutes a better carcass, and a more economical one for the consumer, than a carcass in which gross accumulations of fat are prominent. To add to the educational value of the display, information as to the methods of feeding would be desirable, as it would then be possible to correlate the quality of the meat with the mode of its manufacture. A point of high practical interest is the ratio of carcass weight to fasted live weight, and in the case of prize-winning carcasses these ratios usually fluctuate within very narrow limits. At the 1899 show, for example, the highest proportion of carcass weight to live weight was 68 per cent. in the case of an Aberdeen-Angus steer and of a Cheviot wether, whilst the lowest was 61 per cent., afforded alike by a Shorthorn-Sussex cross-bred heifer and a Mountain lamb. A familiar practical method of estimating carcass weight from live weight is to reckon one

Smithfield stone (8 lb) of carcass for each imperial stone (14 lb) of live weight. This gives carcass weight as equal to 57 per cent. of live weight, a ratio much inferior to the best results obtained at the carcass competition promoted by the Smithfield Club. Table XXI., given as an example,

TABLE XXI.—Block Test, Smithfield Club Show, 1900.

relates to prize carcasses in the competition at the 1900 show.

THE BREEDS OF LIVE STOCK.

In the last quarter of the 19th century the many native breeds of farm live stock became more clearly defined than ever before, and various breeds which at the beginning of that period had received no separate classification in showyard schedules were fully recognized before its close. As a matter of record, it is deemed desirable to notice the breeds as they stand at the beginning of the 20th century. For fuller details than it is here possible to give, the reader should consult the respective stud books, herd books, and flock books pertaining to the several breeds.

Horses.

The breeds of *light* horses include the Thoroughbred, the Yorkshire Coach-horse, the Cleveland Bay, the Hackney, and the pony; of *heavy* horses, the Shire, the Clydesdale, and the Suffolk. The *Thoroughbred* is the oldest of the breeds, and it is known as the "blood-horse" on account of the length of time through which its purity of descent can be traced. It has sprung from the old native horses of England. In past times Arab and Turkish sires were imported for the improvement of the breed, though the use of Eastern blood has, with a few

WELSH BULL, "MADOC BOY."

1st Prize, Royal Agricultural Society's Shows, Birmingham, 1898; York, 1900. The property of, and bred by, Mr. R. M. Greaves, Vern, Porthmadoc, Carnarvonshire.

exceptions, long since been abandoned. The frame of the thoroughbred is light, slender, and graceful; its limbs are clean cut and sinewy, its skin is fine, its hair is glossy, and its eyes are bright and intelligent. Being so highly bred it is apt to be nervous and excitable, and is sometimes unruly, but its speed, resolution, and endurance, as tested on the racecourse, are beyond praise. The demand for *hunting horses* has, during recent years, been productive of useful efforts to improve their quality by crossing thoroughbred stallions with half-bred mares, and work of this nature had been readily undertaken on many horse-breeding farms, stimulated by the premiums offered by the Royal Commission on Horse-breeding. A good type of *hunter horse* should be thick and strong on the back and loin, with long, powerful quarters and muscular thighs, and hocks neatly shaped and clean. The head should be long, lean, and blood-like, and the eye full. A mahogany-brown colour is in high favour, then black, bay, or dark chestnut. Greys, roans, and light chestnuts are less popular.

The *Yorkshire Coach-horse* is extensively bred in the North and East Ridings of York, and the thoroughbred has taken a share in its development. The colour is usually bay or brown, the legs being black. The mane and tail are abundant, but not curly. A fine head, sloping shoulders, strong loins, lengthy quarters, high-stepping action, flat legs, and sound feet are characteristic. The height varies from 16 hands to 16 hands 2 inches. The *Cleveland Bay* is a near relation of the Yorkshire coach-horse, and is bred in various parts of Yorkshire, Durham, and Northumberland. He is adapted alike for the plough, for heavy draught, and for slow saddle work. Some specimens make imposing-looking carriage horses. The colour is light or dark bay, with clean black legs, and black mane and tail. Though rather coarse-headed, the Cleveland Bay has a well-set shoulder and neck, a deep chest, and round barrel. The height is from 16 to 17 hands.

The *Hackney* has come prominently to the front in recent years. The term *Nag*, applied to the active riding or trotting horse, is derived from the Anglo-Saxon *knegan*, to neigh. The Normans brought with them their own word *haquenée*, or *hacquenée*, the French derivative from the Latin *equus*, a horse, whence the name hackney. Both nag and hackney continue to be used as synonymous terms. Frequent mention is made of hackneys and trotters in old farm accounts of the 14th century. The first noteworthy trotting hackney stallion, of the modern type, was a horse foaled about 1755, and variously known as the Schales horse, Shields, or Shales, and most of the recognized hackneys of to-day trace back to him. The breeding of hackneys is extensively pursued in the counties of Norfolk, Cambridge, Huntingdon, Lincoln, and York, and in the showyard competitions a keen but friendly rivalry is usually to be noticed between the hackney-breeding farmers of Norfolk and Yorkshire. Hackneys include both riding horses and driving horses. The aim of the breeder is to produce an animal which is saleable at an early age, which can be bred and reared at moderate expense, and which can be broken in without much risk. Excellent results have followed the use of hackney sires upon half-bred mares, the latter being the offspring of thoroughbred stallions and trotting mares. As regards the movement, or, as it is termed, the "action" of the hackney, he should go light in hand, and the knee should be so elevated and advanced during the trot as to be seen by the rider projecting beyond the breast, whilst, before the foot is put down, the leg should be well extended. Above all, the hackney should possess good hock action, as distinguished from mere fetlock action, the propelling power depending upon the efficiency of the former. To

be classed as a hackney an animal must be over 14 hands high, that is, exceeding 56 inches.

The *Pony* differs essentially from the hackney in the matter of height, the former being required not to exceed 14 hands. There is, however, one exception, the nature of which is made clear in the following extract from Sir Walter Gilbey's *Ponies Past and Present*, 1900:—

Before the establishment of the Hackney Horse Society in 1883 the dividing line between the horse and the pony in England was vague and undefined. It was then found necessary to distinguish clearly between horses and ponies, and, accordingly, all animals measuring 14 hands or under were designated "ponies," and registered in a separate part of the (Hackney) Stud Book. This record of height, with other particulars as to breeding, &c., serves to direct breeders in their choice of sires and dams. The standard of height established by the Hackney Horse Society was accepted and officially recognized by the Royal Agricultural Society in 1889, when the prize-list for the Windsor show contained pony classes for animals not exceeding 14 hands. The altered polo-rule, which fixes the limit of height at 14 hands 2 inches, may be productive of some little confusion; but for all other purposes 14 hands is the recognized *maximum* height of a pony. Prior to 1883 small horses were called indifferently Galloways, hobbies, cobs, or ponies, irrespective of their height.

Native ponies include those variously known as English, New Forest, Exmoor, Dartmoor, Cumberland and Westmorland, Highland, Shetland, and Connemara, the last named comprising—according to Professor J. C. Ewart—five types, viz., Andalusian, Eastern, Cashel, Clydesdale, and Clifden. Ponies range in height from 14 hands down to 8½ or 9 hands, many Shetland ponies not exceeding the latter. As in the case of the hackney, so with the pony, thoroughbred blood has been used, and with good results. One object of the pony breeder is to control size,—to compress the most valuable qualities into the least compass. He endeavours to breed an animal possessing a small head, perfect shoulders, true action, and good manners. A combination of the best points of the hunter with the style and finish of the hackney produces a class of weight-carrying pony which is always saleable.

The *Shire* horse owes its happily-chosen name—to quite recent application, however,—to Arthur Young's remarks, in the description of his agricultural tours during the closing years of the 18th century, concerning the large black old English horse, "the produce principally of the *Shire* counties in the heart of England." Long previous to this, however, the word *Shire*, in connexion with horses, was used in the statutes of Henry VIII. By the various names of the War Horse, the Great Horse, the Old English Black Horse, and the Shire Horse, the breed has for centuries been cultivated in the rich fen-lands of Lincolnshire and Cambridgeshire, and in many counties to the west. The *Shire* is the largest of draught horses, the stallion commonly attaining a height of 17 to 17.3 hands. Though the black colour is still frequently met with, bay and brown are more usually seen. The lighter colours, such as chestnut, roan, and grey, are not so much in favour. With their immense size and weight—1800 lb to 2200 lb—the Shires combine great strength, and they are withal docile and intelligent. They stand on short stout legs, with a plentiful covering—sometimes, perhaps, too abundant—of long hair extending down the back of the limbs from knees and hocks to pasterns. The head is of medium size, and broad between the eyes. The neck is fairly long, and well arched on to the shoulders, which are deep and strong, and moderately oblique. The chest is wide and full, the back short and straight, the ribs are round and deep, the hind quarters long, level, and well let down into the muscular thighs. The cannon-bones should be flat, heavy, and clean, and the feet wide, tough, and prominent at the heels. A good type of *Shire* horse combines symmetrical

outlines and bold free action, with clean, heavy, flat bone, and soft silky hair. Despite the introduction of the motor-car there is a good and remunerative demand for Shire geldings for use as draught horses in towns.

The *Clydesdale*, the Scottish breed of which the native home is in the valley of the Clyde, is not quite so large as the Shire, the average height of stallions being about 16 hands 2 inches. The shoulder is more oblique than in the Shire. The popular colour is bay, particularly if of a dark shade, or dappled. Black is also a common colour, but grey is not encouraged. White markings on one or more of the legs, with a white star or stripe on the face, are quite usual. The "feathering," that is, the development of silky hair on the backs of the legs, as in the Shires, is a point to which Clydesdale breeders attach much importance, it being regarded as an indication of strong, healthy bone. The bones of the legs should be short, flat, clean, and hard. With symmetry, activity, strength, and endurance, the Clydesdale associates a good temper and willing disposition, is easily broken to harness, and makes an admirable draught horse.

The *Suffolk* is a horse quite distinct from the Shire and the Clydesdale, two breeds which possess many points in common. It stands altogether lower, its body looking almost too heavy for its limbs; it possesses a characteristic chestnut or light dun colour, and its legs are free from the "feather" which is so much admired in the two other heavy breeds. How long the Suffolks have been associated with the county after which they are named is unknown, but they are mentioned as long ago as 1586 in Camden's *Britannia*. With an average height of about 16 hands, they often have a weight of as much as 2000 lb, and this may explain the appearance which has given rise to the name of the Suffolk Punch, by which the breed is known. If the Suffolk is not in all respects a handsome animal, he is none the less a resolute and unwearying worker, and is richly endowed with many of the best qualities of a horse.

Cattle.

The recognized breeds of cattle in the British Isles comprise the Shorthorn, Hereford, Devon, South Devon or South Hams, Sussex, Welsh, Longhorn, Red Polled, Aberdeen-Angus, Galloway, Highland, Ayrshire, Jersey, Guernsey, Kerry, and Dexter. These names—with the four exceptions of Shorthorn, Longhorn, Red Polled, and Dexter—are geographical, and serve to indicate the "homes" of the several breeds or the places whence they originated. The Shorthorn, Hereford, Devon, South Devon, Sussex, Longhorn, and Red Polled breeds are native to England; the Aberdeen-Angus, Galloway, Highland, and Ayrshire breeds to Scotland; and the Kerry and Dexter breeds to Ireland. The Jersey and Guernsey breeds—often spoken of as Channel Islands cattle—belong to the respective islands whose names they bear, and great care is taken to keep Jersey cattle out of Guernsey, and Guernsey cattle out of Jersey. The term Alderney is obsolete, and no pure breed is designated by that name.

The *Shorthorn* is the most widely distributed of all the breeds of cattle, both at home and abroad. No census of breeds¹ has ever been taken in the United Kingdom, but such an enumeration would show the Shorthorn far to exceed in numbers any other breed, whilst the great majority of cross-bred cattle contain Shorthorn blood. During the last quarter of the 18th century the brothers Charles Colling (1751-1836) and Robert Colling (1749-1820) set to work, by careful selection and breeding, to

improve the cattle of the Teeswater district in the county of Durham. If the Shorthorn did not actually originate thus, it is indisputable that the efforts of the Collings² had a profound influence upon the fortunes of the breed. It is still termed the Durham breed in most parts of the world except the land of its birth, and the geographical name is far preferable, for the term "shorthorn," describes no characteristic which is not shared by a number of other breeds. Other skilled breeders turned their attention to the Shorthorns and established famous strains, the descendants of which can be traced down to the present day. By Thomas Booth, who dwelt at Killerby and Warlaby in Yorkshire, the "Booth" strains of Shorthorns were originated. Similarly, by Thomas Bates, of Kirklevington in Yorkshire, the "Bates" families were established.³ When Shorthorn breeders of to-day talk of "Booth blood," or of "Bates blood," they refer to animals descended from the respective herds of Thomas Booth and Thomas Bates.

Shorthorns are sometimes spoken of as the ubiquitous breed, and also as the "red, white, and roan" breed. The roan colour is very popular, and the full red has its supporters, as in the case of the Lincolnshire Red Shorthorns; unbroken white is not much in favour. The striking characteristic of the Shorthorn is the ease with which it adapts itself to varying conditions of soil, climate, and management. Add to this that the breed is equally noted both for its beef-making and its milk-yielding properties, and—serving as it thus does the dual purpose—it is not difficult to see why the Shorthorn is so extensively bred over such wide areas. Its importance exceeds that of any other breed, whether it be viewed as a grazier's beast or a dairyman's cow. Shorthorns may be seen at nearly all the fairs and cattle markets of Great Britain and Ireland, a statement that can be made of no other breed. For crossing purposes, for the production of beef-cattle, the Shorthorn is unrivalled.

The culmination of what may be termed the Booth and Bates period was in the year 1875, when the sales took place of Lord Dunmore's and Mr. William Torr's herds, which realized extraordinary prices. In that black year of farming, 1879, prices were declining, and continued to do so till within the last few years of the close of the 19th century, when there set in a gradual revival, stimulated largely by the commercial prosperity of the country. The result of extremely high prices when line-bred animals were in fashion was a tendency to breed from all kinds of animals that were of the same tribe, without selection. Consequently, a deterioration set in, which was aggravated by the overlooking of the milking properties. Shorthorn breeders thus came to see that a change of blood was necessary. Meanwhile, for many years breeders in Aberdeenshire had been holding annual sales of young bulls and heifers from their herds. The late Mr Amos Cruickshank began his annual sales in the 'forties, and the late Mr W. T. Talbot-Crosbie had annual sales from his Shorthorn herd in the south-west of Ireland for a number of years. Many Aberdeen farmers emigrated to Canada, and bought Shorthorn calves in their native county to take with them. The Cruickshanks held their bull sales at that time, and numerous animals were bought by the small breeders in Canada. This continued until 1875, when the Cruickshanks had so much private demand that they discontinued their public sales. Subsequently, when Messrs Cruickshank sold their herd privately to Messrs Nelson for exportation the animals could not all be shipped, and

² C. J. Bates, "The Brothers Colling," *Jour. Roy. Agric. Soc.* 1899.

³ C. J. Bates, *Thomas Bates and the Kirklevington Shorthorns: a Contribution to the History of Pure Durham Cattle.* Newcastle-upon-Tyne, 1897.

¹ In 1900 the bulls of Ireland were for the first time enumerated. There were 8406 Shorthorns, 764 Aberdeen-Angus, 376 Kerries, 329 Herefords, 116 Red Polled, 103 Dexters, 66 Channel Islands, and 4126 others and cross-breeds; total, 14,286.

SHORTHORN COW, "CICELY."

In 1899, 1st Prize, Royal Counties Agricultural Society's Show, Windsor; 1st Prize and Champion, Royal Agricultural Society's Show, Msidstone; 1st Prize and Champion, Highland and Agricultural Society's Show, Edinburgh. In 1900, 1st Prize and Champion, Royal Counties Agricultural Society's Show, Winchester; 1st Prize and Champion, Birmingham Cattle Show; 1st Prize and Shorthorn Champion, Smithfield Club Show. The property of, and bred by, Her Majesty Queen Victoris, the Prince Consort's Shaw Farm, Windsor.

SHORTHORN BULL, "ROYAL DUKE."

In 1899, 1st Prize, Highland and Agricultural Society's Show, Edinburgh. In 1900, 1st Prize and Champion, Royal Dublin Society's Show, Royal Counties Agricultural Society's Show at Winchester, Royal Agricultural Society's Show at York, and Highland and Agricultural Society's Show at Stirling. The property of, and bred by, Her Majesty Queen Victoris, the Prince Consort's Shaw Farm, Windsor.

HEREFORD COW, "TRUTHFUL."
1st Prize, Royal Agricultural Society's Shows, Manchester, 1897; Birmingham, 1898; Maidstone, 1899. 1st Prize, Royal Counties Agricultural Society's Show, Winchester, 1900. The property of, and bred by, Her Majesty Queen Victoria, Flemish Farm, Windsor.

HEREFORD BULL, "EARLSFIELD."
The property of Her Majesty Queen Victoria, Flemish Farm, Windsor; bred by Mr. L. L. Moore, Brampton Brian, Herefordshire. (Never exhibited.)

DEVON COW, "PRETTY."
The property of Her Majesty Queen Victoria, Flemish Farm, Windsor; bred by Mr. F. G. Dingley, Locksley Hall, Komesy, Hants. (Never exhibited.)

DEVON BULL, "QUANTOCK JUBILEE."
The property of Her Majesty Queen Victoria, Flemish Farm, Windsor; bred by Mr. E. J. Stanley, M.P., Quantock Lodge, Bridgwater. (Never exhibited.)

Mr Duthie, of Collynie, Aberdeenshire, bought some of the older cows, whilst Mr Deane Willis, of Bapton Manor, Wilts, bought the yearling heifers. Mr Duthie thereupon resumed the sales that the Cruickshanks had relinquished, his averages being £30 in 1892, about £50 in 1893-94, and £80 in 1895. These prices advanced through English breeders requiring a little change of blood, and also through the increasing tendency to exhibit animals of great substance, or rather to feed animals for show. The success of this movement has strengthened the demand, whilst an inquiry for this line of blood has arisen in the United States and Canada. A faithful contemporary history of the Shorthorn breed is to be found in *Thornton's Circular*, which is published quarterly and dates back to 1868.

The *Hereford* breed is maintained chiefly in Herefordshire and the adjoining counties. Whilst a full red is the general colour of the body, the Herefords are distinguished by their white faces, white chest and abdomen, and white mane. The legs up to the knee or hock are also often white. The horns are moderately long; springing straight from the head in the bull, and turning somewhat forward and upward in the cow. Herefords, though they rear their own calves, have acquired but little fame as dairy cattle. They are, however, very hardy, and produce beef of excellent quality. As, moreover, they are docile they fatten easily and readily, and as graziers' beasts they are in high favour.

The *Devon* cattle—the “Rubies of the West,” as they are termed, in allusion to their colour—are reared chiefly in Devon and Somerset. The colour is a whole red, its depth or richness varying with the individual, and in summer becoming mottled with darker spots. The Devons stand somewhat low; they are neat, compact, and plump, and possess admirable symmetry. Whilst they do not attain the size of the Shorthorn or the Hereford, yet, taking their height into consideration, they perhaps weigh better than either. In the male animal the thick-set horns project straight out at right angles to the rest of the body; in the female they are more slender, and often curve neatly upwards. Being fine-limbed, active animals, they are well adapted for grazing the poor pastures of their native hills, and they turn their food to the best account, yielding excellent beef. They have not yet attained much celebrity as milch kine, for, though their milk is of first-class quality, its quantity is usually small. Latterly, however, the milking qualities have received more attention from breeders, whose object is to qualify the Devon as a dual-purpose breed.

The *South Devon* or *South Hams* cattle are almost restricted to that southern part of the county of Devon known as the Hams, whence they are also called “Hammers.” With a somewhat ungainly head, lemon-yellow hair, yellow skin, and large but hardly handsome udder, the South Devon breed bears far more resemblance to the Guernseys than to the trim-built cattle of the hills of North Devon. The cows are heavy milkers, and furnish excellent butter. They are rarely seen outside their locality, and seldom appear in the showyards.

The *Sussex* breed, named after its native county, resembles the Devon in many respects. The Sussex cattle, however, are bigger, less refined in appearance, less graceful in outline, and of a deeper brown-chestnut colour than the Devons,—the “dainty Devons,” as the latter may well be called in comparison with the massive animals of the Sussex breed. As a hardy race, capable of thriving on poor rough pastures, the Sussex are highly valued in their native districts, where they have been rapidly improved in recent years. They are essentially a beef-producing breed, the cows having little reputation as milkers. By stall-feeding they can be ripened off for the

butcher at an early age. The Sussex cattle are said to “die well,” that is, to yield a large proportion of meat in the best parts of the carcass.

In the *Welsh* breed of cattle black is the prevailing colour, and the horns are long. They do not mature very rapidly, but some of them grow eventually into big ponderous beasts, and their beef is of prime quality. In Wales several varieties are recognized—the Anglesey, Pembroke, Glamorgan—and the cows often acquire considerable reputation as milkers. As graziers' beasts Welsh cattle are well known in the midland counties of England, where, under the name of Welsh runts, large herds of bullocks are fattened upon the pastures, or “topped up” in the yards in winter.

In the *Loughorn* breed of cattle the interest is largely historical. It was with the Longhorns that the famous Robert Bakewell, of Dishley, Leicestershire (1726-95), gave evidence of his remarkable skill as an improver of cattle in the middle of the 18th century.¹ At one period the Longhorns were widely spread in England and Ireland, but, as the Shorthorns extended their domain, the longhorned cattle made way for them. Longhorns are to be seen in the midland counties of England, chiefly in Warwickshire. They are big, rather clumsy animals, with long drooping horns, which are very objectionable in these days of cattle transport by rail and sea, and which sometimes grow in such a fashion as to prevent the animals from grazing. The bullocks feed up to high weights, and the cows are fair milkers. No lover of cattle can view these quaint creatures without a feeling of satisfaction that efforts are being made to resuscitate a breed which has many useful qualities to commend it.

The *Red Polled* is the only hornless breed of English cattle, and, though an old breed, it is within quite recent years that it has come into prominence. These cattle were formerly known as the East Anglian Polls, and later as the Norfolk and Suffolk Polled cattle, being confined chiefly to the two counties named. They are symmetrically-built animals, of medium size, and of uniformly red colour. They have a tuft of hair on the poll, or upper part of the forehead. Of the native breeds of England, the Red Polled have acquired the highest distinction as dairy cattle, and are noted for the length of the period during which they continue in milk. Not less are they valued as beef-producers, and, as they are hardy and docile, they fatten readily and mature fairly early. Hence, like the Shorthorn, they may claim to be a dual-purpose breed. As beef cattle they are always seen to advantage at the Norwich Christmas cattle show, held annually in November.

The *Aberdeen-Angus* breed belongs to Aberdeenshire and adjacent parts of Scotland, but many herds are maintained in England and some in Ireland. They possess glossy black coats (occasionally red), have no horns, and are often termed “Doddies.” They attain great size and weight, make first-class beasts for the butcher, and yield beef of excellent quality. The cross between the Shorthorn and the Aberdeen-Angus, known as the “Blue Grey,” is a favourite in the meat markets.

The *Galloways* are named from the district in the south-west of Scotland to which they are native. Like the Aberdeen-Angus cattle, the Galloways are hornless, and normally of a black colour. But the Galloway, with its thicker hide and shaggy hair, suited to a wet climate, has a coarser appearance than the Aberdeen-Angus, the product of a less humid region, though it approaches the latter in size. The Galloways yield superior beef, but they mature less rapidly than the Aberdeen-Angus. The

¹ Housman, “Robert Bakewell,” *Jour. Roy. Agric. Soc.* 1894.

Galloways make admirable beasts for the grazier, and the cross between the Galloway and the Shorthorn, also known as "Blue Grey," is much sought after by the butcher.

The *Highland* breed—termed also the West Highland and the *Kyloe*—is perhaps the most picturesque of the breeds of British cattle. Their home is amidst the wild romantic scenery of the Highland counties and Western Isles of Scotland, though herds of them may be seen in various English parks. There is no hardier breed. In their native haunts they live exposed to all weathers, and thrive upon scanty herbage which they gather with great effort. They have not made much progress towards early maturity, but their slowly ripened beef is of the choicest quality. Whilst they are not often remarkable for size, they look larger than they really are on account of the thick shaggy hair in which they are enveloped. The colour varies from light dun, or tawny yellow, to black. Their long, handsomely curved horns are set widely apart.

The *Ayrshires* are the dairy breed of Scotland, where they have considerably overstepped the limits of the humid western county whence they take their name. They are usually of a white and brown colour, the patches being well defined. Sometimes the brown is replaced by red, and any one of the colours may prevail to the exclusion of the others. The neat, shapely, upstanding horns, with a peculiar curve upwards at the tip, are characteristic. The *Ayrshires* are of medium size and are graceful movers, and the females have the wedge-shape possessed by typical dairy cows. They are a hardy breed, and give good yields of milk even from poor pastures. The milk of the *Ayrshires* is especially useful for cheesemaking purposes.

The *Jerseys* are a breed of graceful, deer-like cattle whose home is in the island of Jersey, where, by means of stringent regulations against the importation of cattle, the breed has been kept pure for many generations. As its milk is especially rich in fat, the *Jersey* has attained a wide reputation as a butter-producing breed. It is a great favourite in England, where many pure-bred herds exist. The colours most preferred are the light silver-grey, the brown, and the fawn; brindled markings are very rarely seen. The white zone behind the black muzzle gives to these cattle the appearance in respect of which they are sometimes termed "mealy-mouthed." The horns are short, and generally curve inwards; the bones are fine. The best milch cows have a yellowish circle round the eye, and the skin at the extremity of the tail of a deep yellow, almost orange, colour. The *Jersey* cattle possess peculiarities of colour not seen in any other breed in the British Isles. The cows are gentle and docile, but the bulls, despite their small size, are often fierce.

The *Guernsey* cattle have their native homes in the islands of Guernsey, Alderney, Sark, and Herm, and they are kept pure there by the same kinds of restrictions as are adopted in Jersey for the protection of the native breed of that island. Herds of pure-bred *Guernseys* exist in the Isle of Wight and in various southern counties of England. They have not the refined and elegant appearance of the *Jerseys*, which, however, they exceed in size. They are usually of a rich yellowish-brown colour, patched with white, whilst in some cases their colour almost merits the appellation of "orange and lemon." The yellow colour inside the ears is a point always looked for by judges. The cows, large-bellied and narrow in front, are truly wedge-shaped, the greatly developed milk-bag adding to the expanse of the hinder part of the body. They yield an abundance of milk, rich in fat, so that, like the *Jerseys*, they are excellent butter-producers. The horns are yellow at the base, curved, and not coarse. The nose is free from black markings, whereas, in the *Jerseys*,

there is, as has just been stated, a dark muzzle, encircled by a light colour, thus giving a "mealy-mouthed" appearance.

The *Kerry* is a breed of small black cattle belonging to the south-west of Ireland, whence they have spread into many parts, not only of their native land, but of England as well. Although they are able to subsist on the roughest and scantiest of fare, and are exceedingly hardy, the cows are, nevertheless, excellent milkers, and have acquired celebrity as a dairy breed. The colour is black, but the cows sometimes have a little white on the udder. The horns are white, with black tip, and are turned upwards. The *Kerry* is active and graceful, long and lithe in body, and light-limbed.

The *Dexter* breed is an offshoot of the *Kerry*, its origin being attributed to Mr Dexter, who is credited with having established it, by selection and breeding from the best mountain types of the *Kerry*. Until recently it was called the *Dexter Kerry*. It is smaller, shorter in the leg, and more compact than the *Kerry*, and gains in plumpness what it loses in elegance. Whilst valuable as a beef-making animal, it is equally noted for its milk-producing capacity. Black is the usual colour, but red is also recognized, with, in either case, a little white. When of a red colour, its appearance has been aptly compared to that of a grand *Shorthorn* viewed through the wrong end of a telescope. The *Kerry* and the *Dexter* are readily distinguishable. The *Kerry* has a light, deer-like head and horn, light limbs, with ribs, hips, and shoulders well set, thin skin, straight back, light, well-set tail, with long brush. The *Dexter* has, as has just been intimated, very much the character of a diminutive *Shorthorn*, with short strong legs, square body, flat back, thick shoulder, short neck, and well-set head and horn.

The breeds of cattle which are more especially noteworthy as beef-makers include the *Shorthorn*, *Hereford*, *Devon*, *Sussex*, *Welsh*, *Aberdeen-Angus*, *Galloway*, and *Highland*. As milk-producers, and therefore as dairy cattle, the *Shorthorn*, *South Devon*, *Longhorn*, *Red Polled*, *Ayrshire*, *Jersey*, *Guernsey*, *Kerry*, and *Dexter* breeds have acquired eminence. Such breeds as the *Shorthorn*, *Devon*, *Welsh*, *Red Polled*, and *Dexter* are claimed as useful both for beef-making and for milk-producing, and are hence regarded as serving the dual purpose. As regards colour, red is characteristic of the *Hereford*, *Devon*, *Sussex*, and *Red Polled*. Black is the dominating colour of the *Welsh*, *Aberdeen-Angus*, *Galloway*, *Kerry*, and *Dexter*. A yellowish colour is seen in the *Guernsey* and *South Devon* breeds. Various shades of fawn colour are usual in the *Jersey* cattle. The *Herefords*, though with red bodies, have white faces, manes, and dew-laps, whilst white prevails to a greater or less extent in the *Shorthorn*, *Longhorn*, and *Ayrshire* breeds. The *Shorthorn* breed is exceedingly variable in colour; pure-bred specimens may be red, or white, or roan, or may be marked with two or more of these colours, the roan resulting from a blending of the white and red. Black is not seen in a pure-bred *Shorthorn*. With respect to size and weight, the biggest and heaviest cattle come from the beef-making breeds, and are often cross-bred. Very large beasts, if pure-bred, usually belong to one or other of the *Shorthorn*, *Hereford*, *Sussex*, *Welsh*, *Aberdeen-Angus*, and *Galloway* breeds. The *Devon*, *Red Polled*, and *Guernsey* are medium-sized cattle; the *Ayrshires* are smaller. The *Jerseys* are small, graceful cattle, but the *Kerries* and *Dexters* furnish the smallest cattle of the British Isles.

Sheep.

The sheep native to the British Isles may be classified as longwool, shortwool, and mountain breeds. The longwool breeds are the *Leicester*, *Border Leicester*, *Cotswold*,

ABERDEEN-ANGUS COW, "LEGEND,"
1st Prize and Champion, Royal Agricultural Society's Show, Darlington, 1898. The property of, and bred by, Mr. George Smith Grant, Auchorochan, Glenlivet, N.B.

Lincoln, Kentish, Devon Longwool, South Devon, Wensleydale, and Roscommon. The *shortwool* breeds are the Oxford Down, Southdown, Shropshire, Hampshire Down, Suffolk, Ryeland, Somerset and Dorset Horned, and Clun Forest. The *mountain* breeds include the Cheviot, Black-faced Mountain, Herdwick, Lonk, Dartmoor, Exmoor, Welsh Mountain, and Limestone. These breeds are all English, except the Border Leicester, Cheviot and Black-faced Mountain, which belong to Scotland; the Welsh Mountain, which belongs to Wales; and the Roscommon, which is Irish. The true mountain breeds are *horned* sheep—usually the males only in the case of the Cheviot, the Herdwick, and the Welsh, though many Cheviot rams are hornless. In the only other horned breed, the Somerset and Dorset, both sexes are furnished with horns. The remaining breeds are hornless. The white-faced breeds include the Leicester, Border Leicester, Lincoln, Kentish, Cheviot, Ryeland, Devon Longwool, South Devon, Somerset and Dorset Horned, Dartmoor, Exmoor, and Roscommon. Black faces characterize the Hampshire Down and the Suffolk, whilst some amount of black is seen on the faces of the Black-faced Mountain and the Lonk.

The *Leicester*, though sparsely distributed now, is of high interest in that it was the breed which Robert Bakewell took in hand in the 18th century, and greatly improved by the exercise of his skill and judgment. Bakewell lived at Dishley Grange, Leicestershire, and in France the Leicester sheep are still called Dishleys. In past times Leicester blood was extensively employed in the improvement or establishment of other breeds of sheep. The Leicester, as seen now, has a long tapering head, projecting horizontally forwards; rather long, thin ears pointing backwards; a full broad breast; fine clean legs standing well apart; deep round barrel, with the sides diminishing in width towards the rump; thin, soft skin, covered with fine white wool; and the top of the head protected by close short wool. The breed is maintained pure upon the rich pastures of Leicestershire, Yorkshire, and adjacent counties, but its chief value is for crossing, when it is found to promote maturity and to improve the fattening propensity.

The *Border Leicester* originated after the death in 1795 of Bakewell, when the Leicester breed, as it then existed, diverged into two branches. The one is represented by the breed still known in England as the Leicester. The other, bred on the Scottish Borders, acquired the name of Border Leicester. The characteristics of the latter are a sharp profile, with dark, full nostrils, black muzzle, well-set ears, and hair on the face and poll pure white; back broad and muscular, belly well covered with wool; legs clean, and a fleece of fairly long white wool.

The *Cotswold* is an old-established breed of the Gloucestershire hills, extending thence into Oxfordshire. They are big, handsome sheep, with finely-arched necks and graceful carriage. With their broad, straight backs, curved ribs, and capacious quarters, they carry a great weight of carcase upon clean, wide-standing legs. The white silky fleece of long wavy wool gives the Cotswold an attractive appearance, which is enhanced by its stylish topknot or forelock. The mutton of the Cotswolds is not of high quality, but the sheep are useful for crossing purposes, as they impart size.

The *Lincoln* breed is descended from the old native breed of Lincolnshire, improved by the use of Leicester blood. The Lincolns are a hardy, prolific breed, but do not quite equal the Cotswolds in size. They have larger, bolder heads than the Leicesters. Breeders of Lincoln rams like a darkish face, with a few dark spots on the ears. The legs should be white. The wool has a broad staple, and is denser, longer, and the fleece heavier, than

in the Leicester. In 1898 Mr Henry Dudding, Riby Grove, Lincolnshire, obtained at auction the sum of 1000 guineas for a Lincoln ram bred by him, this being the highest price ever paid for a sheep in the United Kingdom. He secured the same price again for a ram in 1900.

The *Kentish* or *Romney Marsh* is a somewhat local breed, native to the rich tract of grazing land on the south coast of Kent. They are hardy, white-faced sheep, with a close-coated longwool fleece.

The *Oxford Down* is a modern breed which owes its origin to the cross-breeding of longwool and shortwool sheep, the former being Cotswolds and the latter Hampshire Downs and Southdowns. Although it has inherited the forelock from its longwool ancestors, it approximates more nearly to the shortwool type, and is accordingly classified as such. An Oxford Down ram has a bold masculine head; a poll well covered with wool, and adorned by a topknot; ears self-coloured, upright, and of fair length; face of uniform dark brown colour; legs short, dark in colour, and free from spots; back level and chest wide; and the fleece heavy and thick. The breed is popular in Oxford and other midland counties.

The *Southdown* was formerly known as the Sussex Down, as it was from the short, close pastures upon the chalky soils of the South Downs in Sussex that the breed sprang. In past times it did for the improvement of the shortwool breeds of sheep very much the same kind of work that the Leicester performed in the case of the longwool breeds. A pure-bred Southdown sheep has a small head, with a light brown or brownish grey (often mouse-coloured) face, fine bone, and a symmetrical, well-fleshed body. The legs are short and neat, the animal being of small size compared with the other Down sheep. The fleece is of fine, close, short wool, and the mutton is excellent.

The *Shropshire* is descended from the old native sheep of the Salopian hills, improved by the use of Southdown blood. Though heavier in fleece and a bulkier animal, the Shropshire has resemblance to an enlarged Southdown. As distinguished from the latter, however, the Shropshire has a darker face, blackish brown as a rule, with very neat ears, whilst its head is more massive, and is better covered with wool on the top and at the sides. This breed has made rapid strides in recent years, and it has acquired favour in Scotland and Ireland as well as abroad.

The *Hampshire Down* is another breed which owes much of its improved character to an infusion of Southdown blood. Early in the 19th century the old Wiltshire horned sheep and the Berkshire Knot roamed over the Downs of their native counties. Both these old-fashioned types have disappeared, but their descendants are seen in the modern Hampshire Down, which originated in a cross with the Southdown. Early maturity and great size have been the objects aimed at and attained, this breed, more perhaps than any other, being identified with early maturity. Whilst heavier than the Shropshire, the Hampshire Down sheep is less symmetrical. The Hampshire Downs have black faces and legs, big heads with Roman nose, darkish ears set well back, and a broad level back nicely filled in with lean meat. The mutton of the Down breeds is of superior quality.

The *Suffolk* is another modern breed, which probably took its origin in the crossing of improved Southdown rams with the old horned Norfolk ewes. The characteristics of the latter are still retained in the black face and legs of the Suffolk, but the horns have been improved away. The fleece is moderately short, the wool being of close, fine, lustrous fibre, without any tendency to mat together. The limbs, woolled to the knees and hocks, are clean below. In general appearance the Suffolk is like

the Hampshire Down, from which it differs in the rather darker face, head less covered with wool, and the nose of a less pronounced Roman type.

The *Cheviot* takes its name from the range of hills extending along the boundary between England and Scotland, on both sides of which the breed now extends, though its origin has to be sought in Northumberland. The Cheviot is a hardy sheep with straight wool, of moderate length and very close-set, whilst wiry white hair covers the face and legs.

The *Black-faced Mountain* breed is chiefly reared in Scotland; but it is doubtful whether its origin is English or Scottish. Their greater hardiness, as compared with the Cheviots, has brought them into favour upon the higher grounds of the north of England and of Scotland, where they thrive upon coarse and exposed grazing lands. The colour of face and legs in this hardy mountain breed is well-defined black and white, the black predominating. The horns are low at the crown, with a clear space between the roots, and sweep away in a wide curve, sloping slightly backwards, and quite clear of the cheek. The fashionable fleece is deep, hairy, and strong, and of uniform quality throughout.

The *Lonk* has its home amongst the hills of Lancashire and Yorkshire, and it is the largest of the mountain breeds. It bears most resemblance to the Black-faced Mountain sheep, but carries a finer, heavier fleece, and is larger in head and body. Its face and legs are mottled white and black, and its horns are handsome. The tail is long and rough.

The *Herdwick* is a hardy breed thriving upon the poor mountain land in Cumberland and Westmorland. The rams sometimes have curved horns. The colour of these sheep is white, with a few darkish spots here and there; the faces and legs are often speckled. The wool is strong, coarse, and open, and inclined to be hairy about the neck. The forehead has a topknot, and the tail is broad and bushy.

The *Wensleydale* takes its name from the Yorkshire dale (Yoredale) of which Thirsk is the centre. The Wensleydales are longwool sheep, derived from the old Teeswater breed by crossing with Leicester rams. They are dark-faced, and the head is broad and flat, with a tuft of wool on the forehead. The skin is blue, fine, and soft, whilst the wool has a bright lustre, is curled in all parts of the body, and is of uniform staple. The fore-legs are set well apart, and the hind-legs have a little fine wool below the hock.

The *Limestone* is a breed of which little is heard. It is almost restricted to the fells of Westmorland, and is probably nearly related to the Black-faced Mountain breed. The so-called "Limestones" of the Derbyshire hills are really Leicesters.

The *Welsh Mountain* is a small, active, soft-wooled, white-faced breed of hardy character. The legs are often brownish, and this colour may extend to the face. Horns may or may not be present. The mutton is of excellent quality.

The *Clun Forest* is a local breed in West Shropshire and the adjacent part of Wales. It is descended from the old tan-faced sheep that once occupied the district, and has been much crossed with the Shropshire sheep, but its wool is rather coarser than that of the latter. The first cross with the Shropshire is a favourite with butchers.

The *Ryeland* breed is so named from the Ryelands, a poor upland district in Herefordshire. It is a very old breed, against which the Shropshires have made substantial headway. The Ryeland sheep are small, hornless, have white faces and legs, and remarkably fine short wool, with a topknot on the forehead.

The *Somerset and Dorset Horned* is an old west-country breed of sheep. The fleece is of close texture, and the wool is intermediate between long and short, whilst the head carries a forelock. Both sexes have horns, which are very much coiled in the ram. The muzzle, legs, and hoofs are white; the nostrils are pink. This is a hardy breed, in size somewhat exceeding the Southdown. Two crops of lambs in a year are sometimes obtained from the ewes, the winter lambs being dropped from October onwards.

The *Devon Longwool* is a breed locally developed in the valleys of West Somerset, North and East Devon, and parts of Cornwall. It originated in a strong infusion of Leicester blood amongst the old Bampton stock of Devonshire. The Devon Longwool is not unlike the Lincoln, but is coarser. It is white-faced, with a lock of wool on the forehead.

The *South Devon* or *South Hams* are, like the cattle of that name, a strictly local breed, which likewise exemplify the good results of crossing with the Leicesters. The South Devons have a fairly fine silky fleece of long staple.

The *Dartmoor* is a hornless, longwool, white-fleeced sheep, with a long whitish face like that of the Leicester. It is a hardy local Devonshire breed, and is much larger than the Exmoor.

The *Exmoor* is a horned breed of Devonshire moorland sheep, probably of direct descent from the old forest or mountain breeds of England. They have white legs and faces and black nostrils. The horns curl more closely against the head than in the Somerset and Dorset breed. The Exmoors are delicately formed about the head and neck, and they have a close, fine fleece of short wool. They are very hardy, and yield mutton of choice flavour.

The *Roscommon*—the one breed of modern sheep native to Ireland—is indebted for its good qualities largely to the use of Leicester blood. It is a big-bodied sheep, carrying a long, wavy, silky fleece. It ranges mainly from the middle of Ireland westwards.

Pigs.

The classification of the native breeds of pigs compares unfavourably with that of either cattle or sheep, and in many parts of England there are nondescript animals which it would be difficult to assign to any of the recognized breeds. The latter include the Large White, Middle White, and Small White, which were all formerly embraced under the general term of Yorkshires, and are still so called in other countries. The Berkshire and the so-called Black breeds (Suffolk or Essex) are black, and the Tamworths are red.

The *Large Whites* often have a few blue spots in the skin. The head is of fair length, light in the jowls, and wide between the eyes, with somewhat drooping ears. The neck is long, but not coarse, the ribs are deep, the loin is wide and level, the tail is set high, and the legs are straight and set well outside the carcass. The whole body is covered with straight silky hair, which denotes quality and lean meat. Pigs of this breed are very prolific, and they may be grown to enormous weights.

The *Middle Whites* are built on a smaller scale than the Large Whites. They are shorter in the heads and legs, thicker and more compact in the body, and have a denser clothing of silky hair. The sows are quite as prolific as those of the Large White breed, and, as their produce matures earlier, they are much in demand for breeding porkers.

The *Small White* pigs are much smaller than the Middle Whites. The head and legs are very short, and the body, which is short, thick, and wide, is close to the ground. The jowls are heavy, the ears are pricked, and the thin skin

is laden with long silky hair, wavy, but not curly, whilst the tail is very fine. A deficiency of lean meat is a common characteristic of the breed.

The *Small Black* (Suffolk or Essex) breed resembles the Small White, except that the skin is coal-black in colour, and the coat of hair is not usually profuse. The Small Black, moreover, is rather longer, and stands somewhat higher, whilst it yields more lean meat than the Small White. It matures early and is quick to fatten. A closely similar pig to this of the eastern counties of England thrives in Dorset, Devon, and Cornwall.

The *Large Black* breed has only recently received show-yard recognition, but it is claimed that there is ample evidence that, with its characteristic whole colour, length, fine hair, lop ear, and great grazing capacity, the Large Black existed in many parts of England long previously to the memory of any of the present generation of breeders. It has been continuously and carefully bred in Cornwall, Devon, Essex, Suffolk, and more recently in Yorkshire, Somerset, Norfolk, and Hampshire. Large Blacks are exceedingly docile, and the natural carriage of the ears, well forward over the eyes, is said to contribute materially to a quietness of habit which renders them peculiarly adapted to field grazing. On account of their hardiness and disposition to early maturity they have proved valuable for crossing purposes in Cumberland, Yorkshire, and other counties. The Large Black Pig Society was incorporated so recently as 1899.

The *Berkshire*, though a black pig, usually has a white blaze or mark down the face, a white tip to the tail, and feet white up to the ankle joint. It has a moderately short head with heavy jowls, a deep carcase, wide, low, and well-developed hind-quarters, with heavy hams. The skin is free from rucks and lines, and carries an abundance of fine hair.

The *Tamworth* is one of the oldest breeds of pigs. The colour is red, with darkish spots on the skin. The head, body, and legs are long, and the ribs are deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now much more extensively bred, and is valued as a bacon pig.

The enormous imports of bacon and hams into the United Kingdom—amounting in the year 1900 to 7,443,918 cwt., valued at £15,995,786—has led to the bestowal of greater attention upon the bacon-producing industry at home. In spite of all foreign competition, English bacon and hams command the highest prices, for there is something in the English method of feeding and curing which is equivalent to an addition of so many shillings per cwt. to the price. Much information on this subject is contained in the papers¹ by Mr L. M. Douglas, which may be consulted for fuller details.

BREED SOCIETIES.

A noteworthy feature of the closing decades of the 19th century was the formation of voluntary associations of stockbreeders, with the object of promoting the interests of the respective breeds of live stock. As a typical example of these organizations the Shire Horse Society may be mentioned. It was incorporated in 1878 to improve and promote the breeding of the Shire or old English race of cart horses, and to effect the distribution of sound and healthy sires throughout the country. Up to the year 1901 inclusive the society had held twenty-two annual shows in London, and had distributed prizes of an aggregate value of nearly £19,000, besides offering gold and

silver medals for competition amongst Shire horses at agricultural shows in different parts of the country. Twenty-two annual volumes of the *Shire Horse Stud Book* had been published, recording the pedigrees of 19,275 stallions and 34,578 mares, or a total of 53,853 animals. In 1901 the society possessed more than 3000 members, paying an annual subscription of one guinea, or a life composition of ten guineas. It is out of the funds thus obtained that the society has carried on a work of high national importance, and has effected a marked improvement in the character and quality of the Shire horse. What has thus voluntarily been done in England would in most other countries be left to the state, or would not be attempted at all. It is hardly necessary to say that the Shire Horse Society has never received a penny of public money, nor has any other of the voluntary breeders' societies. The Hackney Horse Society and the Hunters' Improvement Society are conducted on much the same lines as the Shire Horse Society, and, like it, they each hold a show in London in the spring of the year and publish an annual volume. Other horse-breeders' associations, all doing useful work in the interests of their respective breeds, are the Suffolk Horse Society, the Clydesdale Horse Society, the Yorkshire Coach Horse Society, the Cleveland Bay Horse Society, the Polo Pony Society, the Shetland Pony Stud Book Society, and the Association for the Improvement of New Forest Ponies. Thoroughbred race-horses are registered in the General Stud Book. The Royal Commission on Horse Breeding, which dates from 1887, is, as its name implies, not a voluntary organization. Through the commission the money previously spent upon Queen's Plates is offered in the form of "Queen's Premiums" ("King's Premiums" in 1901 and subsequent years) of £150 each for thoroughbred stallions, on condition that each stallion winning a premium shall serve not less than fifty half-bred mares, if required. The winning stallions are distributed in districts throughout Great Britain, and the use of these selected sires has resulted in a decided improvement in the quality of half-bred horses. The annual show of the Royal Commission on Horse Breeding is held in London jointly and concurrently with those of the Hunters' Improvement Society and the Polo Pony Society. At the 1901 show 29 premiums of £150 were offered for thoroughbred stallions over 4 years old and not exceeding 20 years.

Of organizations of cattle-breeders the English Jersey Cattle Society, established in 1878, may be taken as an illustrative type. It offers prizes in butter-test competitions and milking trials at various agricultural shows, and publishes the *English Herd Book and Register of Pure-bred Jersey Cattle*, of which the tenth volume was issued in 1899. This volume records the births in the herds of members of the society, and gives the pedigrees of 1178 cows and 337 bulls, besides furnishing lists of prize-winners at the principal shows and butter-test awards, and reports of sales by auction of Jersey cattle. Other cattle societies, all well caring for the interests of their respective breeds, are the Shorthorn Society of Great Britain and Ireland, the Lincolnshire Red Shorthorn Association, the Hereford Herd Book Society, the Hereford Cattle Breeders' Association (the two last-named are now amalgamated), the Devon Cattle Breeders' Society, the South Devon Herd Book Society, the Sussex Herd Book Society, the Longhorned Cattle Society, the Red Polled Society, the English Guernsey Cattle Society, the English Kerry and Dexter Cattle Society, the North Wales Black Cattle Society, the Polled Cattle Society (for the Aberdeen-Angus breed), the English Aberdeen-Angus Cattle Association, the Galloway Cattle Society, the Ayrshire Cattle Herd Book Society, and the Highland Cattle Society of Scotland.

¹ "Bacon Curing," *Jour. Roy. Agric. Soc.*, 1898; and "The Construction of a Modern Bacon Factory," *Ibid.* 1900.

In the case of sheep the National Sheep Breeders' Association looks after the interests of flockmasters in general, whilst most of the pure breeds are represented also by separate organizations. The Hampshire Down Sheep Breeders' Association may be taken as a type of the latter, its principal object being to encourage the breeding of Hampshire Down sheep at home and abroad, and to maintain the purity of the breed. It publishes an annual Flock Book, the first volume of which appeared in 1890. In this book are named the recognized and pure-bred sires which have been used, and ewes which have been bred from, whilst there are also registered the pedigrees of such sheep as are proved to be eligible for entry. Prizes are offered by the society at various agricultural shows where Hampshire Down sheep are exhibited. Other sheep societies include the Leicester Sheep Breeders' Association, the Cotswold Sheep Society, the Lincoln Longwool Sheep Breeders' Association, the Oxford Down Sheep Breeders' Association, the Shropshire Sheep Breeders' Association and Flock Book Society, the Southdown Sheep Society, the Suffolk Sheep Society, the Border Leicester Sheep Breeders' Society, the Wensleydale Longwool Sheep Breeders' Association and Flock Book Society, the Incorporated Wensleydale Blue-faced Sheep Breeders' Association and Flock Book Society, the Kent Sheep Breeders' Association, the Devon Longwool Sheep Breeders' Society, the Dorset Horn Sheep Breeders' Association, the Cheviot Sheep Society, and the Roscommon Sheep Breeders' Association.

The interests of pig breeders are the care of the National Pig Breeders' Association, in addition to which there exist the British Berkshire Society and the Large Black Pig Society.

The addresses of the secretaries of the various livestock societies in the United Kingdom are published annually in the *Live Stock Journal Almanac*.

THE MAINTENANCE OF THE HEALTH OF LIVE STOCK.

It was not till the closing decade of the 19th century that the stock-breeders of the United Kingdom found themselves in a position to prosecute their industry free from the fear of the introduction of contagious disease through the medium of store animals imported from abroad for fattening on the native pastures. By the Diseases of Animals Act, 1896 (59 & 60 Vict. c. 15), it was provided that cattle, sheep, and pigs imported into the United Kingdom should be slaughtered at the place of landing. The effect was to reduce to a *minimum* the risk of the introduction of disease amongst the herds and flocks of the country, and at the same time to confine the trade in store stock exclusively to the breeders of Great Britain and Ireland. This arrangement makes no difference to the food-supply of the people, for dead meat continues to arrive at British ports in ever-increasing quantity. Moreover, live animals are admitted freely from certain countries, provided such animals are slaughtered at the place of landing. At Deptford, for example, large numbers of cattle and sheep which thus arrive—mainly from Argentina, Canada, and the United States—are at once slaughtered, and so furnish a steady supply of fresh-killed beef and mutton. The animals which are shipped in this way are necessarily of the best quality, because the freight on a superior beast is no more costly than on an inferior one, and the proportion of freight to sale price is therefore less. With this superior description of butchers' stock all classes of home-grown stock—good, bad, and indifferent—have, of course, to compete. The Board of Agriculture has the power to close the ports of the United Kingdom against live animals from any country in which

contagious disease is known to exist. This accounts for the circumstance that so few countries—none of them in Europe—enjoy the privilege of sending live animals to British ports. So recently as 1900, the discovery early in that year of the existence of foot-and-mouth disease amongst cattle and sheep shipped from Argentina to the United Kingdom led to the issue of an order, by which all British ports were closed against live animals from the country named. This order came into force on 30th April, and was still in operation a year later, with the result that there was a marked decline in the shipments of live cattle and sheep from the River Plate, but a decided increase in the quantity of frozen meat sent thence to the United Kingdom.

The last quarter of the 19th century witnessed an important change in the attitude of public opinion towards legislative control over the contagious diseases of animals. When, after the introduction of cattle plague or rinderpest in 1865, the proposal was made to resort to the extreme remedy of slaughter in order to check the ravages of a disease which was pursuing its course with ruinous results, the idea was received with public indignation and denounced as barbarous. Views have undergone profound modification since then, and the most drastic remedy has come to be regarded as the most effective, and in the long run the least costly. The Cattle Diseases Prevention Act, 1866 (29 & 30 Vict. c. 2), made compulsory the slaughter of diseased cattle, and permitted the slaughter of cattle which had been exposed to infection, compensation being provided out of the rates. The Act 30 & 31 Vict. c. 125, 1867, is of historical interest, in that it contains the first mention of pleuro-pneumonia, and the exposure in any market of cattle suffering from that disease was made an offence. The Contagious Diseases (Animals) Act, 1869 (32 & 33 Vict. c. 70), revoked all former Acts, and defined disease to mean cattle plague, pleuro-pneumonia, foot-and-mouth disease, sheep-pox, sheep-scab, and glanders, together with any disease which the Privy Council might by order specify. The principle of this Act in regard to foreign animals was that of free importation, with power for the Privy Council to prohibit or subject to quarantine and slaughter, as circumstances seemed to require. The Act of 1869 was at that time the most complete measure that had ever been passed for dealing with diseases of animals. The re-introduction of cattle plague into England in 1877 led to the passing of the Act 41 & 42 Vict. c. 74, 1878, which repealed the Act of 1869, and affirmed as a principle the landing of foreign animals for slaughter only, though free importation or quarantine on the one hand and prohibition on the other were provided for in exceptional circumstances. By an Order of Council which came into operation in December 1878, swine fever was declared to be a disease for the purposes of the Act of that year. It was not, however, till October 1886 that anthrax and rabies were officially declared to be contagious diseases for the purposes of certain sections of the Act of 1878. In 1884 the Act 47 & 48 Vict. c. 13 empowered the Privy Council to prohibit the landing of animals from any country in respect of which the circumstances were not such as to afford reasonable security against the introduction of foot-and-mouth disease. After one or two other measures of minor importance came the Act 53 & 54 Vict. c. 14, known as the Pleuro-pneumonia Act of 1890, which transferred the powers of local authorities to slaughter and pay compensation in cases of pleuro-pneumonia to the Board of Agriculture, and provided further for the payment of such compensation out of money specifically voted by Parliament. This measure was regarded at the time as a marked step in advance, and was only carried after a vigorous campaign in its favour. In 1892, by the Act

55 & 56 Vict. c. 47, power was given to the Board of Agriculture to use the sums voted on account of pleuro-pneumonia for paying the costs involved in dealing with foot-and-mouth disease; under this Act the Board could order the slaughter of diseased animals and of animals in contact with these, and could pay compensation for animals so slaughtered. Under the provisions of the Contagious Diseases (Animals) Act, 1893 (56 & 57 Vict. c. 43) swine fever in Great Britain was, from 1st November in that year, dealt with by the Board of Agriculture in the same way as pleuro-pneumonia, the slaughter of infected swine being carried out under directions from the central authority, and compensation allowed from the imperial exchequer. In 1894 was passed the Diseases of Animals Act (57 & 58 Vict. c. 57), the word "contagious" being omitted from the title. This was a measure to consolidate the Contagious Diseases (Animals) Acts, 1878 to 1893. In it "the expression 'disease' means cattle plague (that is to say, rinderpest, or the disease commonly called cattle plague), contagious pleuro-pneumonia of cattle (in this Act called pleuro-pneumonia), foot-and-mouth disease, sheep-pox, sheep-scab, or swine fever (that is to say, the disease known as typhoid fever of swine, soldier purples, red disease, hog cholera or swine plague)." The Diseases of Animals Act, 1896 (59 & 60 Vict. c. 15)—the last of the series of such Acts passed in the 19th century—rendered compulsory the slaughter of imported live stock at the place of landing, a boon for which British stock-breeders had striven for many years. The ports in Great Britain at which foreign animals may be landed are Bristol, Cardiff, Glasgow, Hull, Liverpool, London, Manchester, and Newcastle-upon-Tyne. Animals from the Channel Islands may be landed at Southampton.

THE DISEASES OF ANIMALS.

Under the Diseases of Animals Acts, 1894 and 1896, weekly returns are issued by the Board of Agriculture of outbreaks of anthrax, foot-and-mouth disease, glanders (including farcy), pleuro-pneumonia, rabies, and swine fever in the counties of Great Britain; also monthly returns of outbreaks of sheep-scab. There is a popular notion that tuberculosis is included amongst the diseases scheduled under the Diseases of Animals Act, but this is not (1901) the case.

Cattle plague, or rinderpest, has not been recorded in Great Britain since 1877. In that year there were 47 outbreaks distributed over five counties, and involving 263 head of cattle.

The course of *foot-and-mouth* disease in Great Britain between 1877 and 1900 inclusive is told in Table XXII.

TABLE XXII.—*Outbreaks of Foot-and-Mouth Disease in Great Britain, 1877 to 1900.*

Year.	Counties.	Outbreaks.	Animals attacked.			
			Cattle.	Sheep.	Swine.	Other Animals.
1877	55	858	5,640	7,405	2,099	
1878	45	235	912	8,609	245	
1879	29	137	261	15,681	5	
1880	38	1,461	20,918	9,572	1,886	2
1881	49	4,833	59,484	117,152	6,330	80
1882	49	1,970	23,973	11,412	2,564	1
1883	75	18,732	219,289	217,492	24,332	32
1884	55	949	12,186	14,174	1,860	1
1885	10	30	354	34	30	
1886	1	1	10			
1892	15	95	1,248	3,412	107	
1893	2	2	30			
1894	3	3	7	261		
1900	9	21	214	50	2	

both inclusive, are omitted, because there was no outbreak during those periods. The disease is seen to have attained its *maximum* virulence in 1883.

Sheep-scab, a loathsome skin disease due to an acarian parasite, is in a most unsatisfactory position in Great Britain. Table XXIII. shows the number of outbreaks,

TABLE XXIII.—*Outbreaks of Sheep-Scab in Great Britain, 1877 to 1900.*

Year.	Counties.	Outbreaks.	Year.	Counties.	Outbreaks.
1877	77	3214	1889	75	1207
1878	75	2335	1890	75	1506
1879	83	2229	1891	80	2250
1880	70	1556	1892	82	2821
1881	77	2055	1893	86	2603
1882	78	2234	1894	84	2811
1883	73	1898	1895	88	3092
1884	73	1509	1896	79	3536
1885	69	1512	1897	80	2191
1886	74	1502	1898	79	2514
1887	75	1596	1899	79	2056
1888	72	1260	1900	78	1939

and the number of counties over which they were distributed, in each year from 1877 to 1900. The outbreaks are seen to have been more numerous in the decade of the 'nineties than in that of the 'eighties, though possibly this may have been due to greater official activity in the later period. The number of sheep attacked each year has ranged between 68,715 in 1877 and 18,762 in 1888. It is compulsory on owners to notify the authorities as to the existence of scab amongst their sheep, but there is no general or well-defined method of suppressing the disorder, and the periodical dipping of sheep for the destruction of the scab parasite is not obligatory. Each year the disorder runs a similar course, the outbreaks dwindling to a *minimum* in the summer months, June to August, and attaining a maximum in the winter months, December to February. It is chiefly in the "flying" flocks and not in the breeding flocks that the disease is rife, and it is so easily communicable that a drove of scab-infested sheep passing along a road may leave behind them traces sufficient to set up the disorder in a drove of healthy sheep that may follow. For its size and in relation to its sheep population, Wales harbours the disease to a far greater extent than the other divisions of Great Britain, as the following numbers of outbreaks in the three years 1898 to 1900 serve to show:—

Year.	England.	Wales.	Scotland.	Great Britain.
1898	1342	1038	135	2515
1899	1123	791	142	2056
1900	932	917	90	1939
Total, 3 years.	3397	2746	367	6510

The fatal disease known as *anthrax* did not form the subject of official returns previous to the passing of the Anthrax Order of 1886. Isolated outbreaks are of common occurrence, and from the totals for Great Britain given in Table XXIV. it would appear that there is little prospect of the eradication of this bacterial disorder.

Glanders (including farcy) has been the subject, during the twenty-four years 1877 to 1900, of outbreaks in Great Britain ranging between a *minimum* of 518 in 1877 and a *maximum* of 1657 in 1892; in the former year 758 horses were attacked, and in the latter 3001. A recrudescence of the disease marked the closing years of the 19th century, the outbreaks having been 748 in 1898, 853 in 1899, and 1119 in 1900. The counties of Great Britain over which the annual outbreaks have been

from which the years 1887 to 1891 and 1895 to 1899,

distributed have ranged between 24 in 1890 and 52 in 1879. As a matter of fact, however, the disease is

strongly centred upon the metropolitan area, more than half of the outbreaks being reported from the county of London alone.

The Rabies Order was passed in 1886, and the number of counties in Great Britain in which cases of rabies in dogs have been reported in each subsequent year is shown in Table XXV. In addition there have been some cases of rabies in animals other than dogs. The disease was very rife in 1895, but the extensive application of the muzzling restrictions of the Board of Agriculture was accompanied by so steady a diminution in the

prevalence of the disease that it was thought the latter had been extirpated. The entire revocation of the muzzling order which accordingly followed proved, however, to be premature, and it became necessary to reimpose it in the districts where it had last been operative, namely, certain parts of South Wales.

Pleuro-pneumonia in Great Britain was dealt with by the local authorities up to the year 1890. Between 1870 and 1889 the annual outbreaks had ranged between a *minimum* of 312 in 1884 and a *maximum* of 3262 in 1874, the largest number of cattle attacked in any one year being 7983 in 1872. The largest number of counties over which the outbreaks were distributed was 72 in 1873. On 1st September 1890, the Board of Agriculture assumed powers with respect to pleuro-pneumonia under the Diseases of Animals Act of that year. Their administration was attended by success, for from 192 outbreaks in Great Britain in 1891 the total fell to 35 in 1892, and to nine in 1893. In the four subsequent years, 1893 to 1897, the outbreaks numbered two, one, two, and seven respectively. In January 1898 an outbreak was discovered in a London cow-shed. This proved to be the last case in the 19th century of what at one time had been a veritable scourge to cattle-owners, and a source of heavy financial loss.

¹ In 1889 the animals attacked included 461 deer.

² Before 1893, horses, asses, and mules were not included in the word "animals" in the Orders relating to anthrax.

The record of *swine fever* in Great Britain is discouraging. Between 1879 and 1892 inclusive, the administration was entrusted to local authorities. The largest number of outbreaks reported in any one of those years was 7926 in 1885, and the smallest 1717 in 1881. In 1893 the Board of Agriculture took over the management, and Table XXVI. shows the number of counties in which

TABLE XXVI.—*Outbreaks of Swine Fever in Great Britain, 1894 to 1900.*

swine fever existed, the number of outbreaks confirmed, and the number of swine slaughtered by order of the Board in each year since. The trouble with this disease is mainly in England, the outbreaks in Wales and Scotland being comparatively few. What are termed "Swine-fever infected areas" are scheduled by the Board when and where circumstances seem to require, and the movement of swine within such areas is prohibited, much inconvenience to trade resulting from restrictions of this kind. Frequently, moreover, the exhibition of pigs at agricultural shows has to be abandoned in consequence of these swine-fever regulations.

THE TRADE IN LIVE STOCK BETWEEN IRELAND AND GREAT BRITAIN.

The compulsory slaughter at the place of landing does not extend to animals shipped from Ireland into Great Britain, and this is a matter of the highest importance to Irish stockbreeders, who find their best market close at hand on the east of St George's Channel. Table XXVII.

TABLE XXVII.—*Imports of Live Stock from Ireland into Great Britain, 1891 to 1900.*

shows the numbers of cattle, sheep, and pigs shipped from Ireland into Great Britain in each of the ten years 1891 to 1900, the numbers of horses similarly shipped being also indicated. On the average rather more than half the total of cattle is made up of store animals for fattening or breeding purposes, the fattening of Irish stores being a business of considerable magnitude in Norfolk and other counties. Calves constitute about one-twelfth of the total number of cattle. Most of the pigs sent from Ireland into Great Britain are fat, the store pigs accounting for less than one-tenth of the total number. The returns from Ireland under the Diseases of Animals Acts, 1894 and 1896, are less significant than those of Great Britain. Thus, in 1900, they included 2 outbreaks of anthrax, 10 of glanders, 233 of swine fever, and 545 of sheep-scab, together with 15 cases of rabies. Compared with the export trade in live stock from Ireland

to Great Britain the reciprocal trade from Great Britain to Ireland is small, and is largely restricted to animals for breeding purposes. Owing to the reappearance of foot-and-mouth disease in Great Britain early in 1900 the importation of cattle, sheep, goats, and swine therefrom into Ireland was temporarily suspended by the authorities in the latter country.

EXPORTS OF ANIMALS FROM THE UNITED KINGDOM.

The general export trade of the United Kingdom in living animals represents an aggregate average annual value, over the five years 1896 to 1900, of £1,017,000. To this sum of rather more than one million sterling the value of horses alone contributes three-fourths, Belgium taking more than half the number of exported horses. The export trade in cattle, sheep, and pigs is practically restricted to pedigree animals required for breeding purposes, and though its aggregate value is not large it is of considerable importance to stockbreeders, as it is a frequent occurrence for buyers for export—to Argentina, Australasia, Canada, the United States, and elsewhere—to bid freely at the sale rings, and often to pay the highest prices, thus stimulating the sales and encouraging the breeding of the best types of native stock. Details for the five years 1896 to 1900 are summarised in Table XXVIII.

CROPS AND CROPPING.

The greater freedom of cropping and the less close adherence to the formal system of rotation of crops, which characterized the later years of the 19th century, rest upon a scientific basis. Experimental inquiry has done much to enlighten the farmer as to the requirements of plant-life, and to enable him to see how best to meet these requirements in the case of field crops. He cannot afford to ignore the results that have been gradually accumulated—the truths that have been slowly established—at the agricultural experiment stations in various parts of the world. Of these stations the greatest, and the oldest now existing, is that at Rothamsted, Harpenden, Herts, England; and

Rothamsted.

it will be expedient before discussing the lessons which Rothamsted has taught, to refer briefly to the origin and scope of the work of a centre of investigation the name of which is known and honoured in all countries where progressive agriculture is practised. The agricultural experiment station at Rothamsted was founded in 1843 by the late Sir John Bennet Lawes, and maintained at his own expense; whilst he made provision for its continuance by putting in trust during his lifetime £100,000, the laboratories, and certain areas of land, which since 1889 have been administered by the Lawes Agricultural Trust Committee. Sir J. Henry Gilbert became associated with Sir John Lawes in 1843 as director of the chemical laboratory, and the collaboration thus commenced was terminated only by the death of the founder

on 31st August 1900. The results of more than half a century of sustained experimental inquiry have been communicated to the world by Lawes and Gilbert in about 130 separate papers or reports, many of which were published, from 1847 onwards, in the *Journal of the Royal Agricultural Society of England*.

Two main lines of inquiry have been followed, the one relating to plants, the other to animals. In the case of plants the method of procedure has been to grow some of the most important crops of rotation, each separately year after year, for many years in succession on the same land, (a) without manure, (b) with farmyard manure, and (c) with a great variety of chemical manures; the same description of manure being, as a rule, applied year after year on the same plot. Experiments on an actual course of rotation, without manure, and with different manures, have also been made. Wheat, barley, oats, beans, clover, and other leguminous plants, turnips, sugar beet, mangels, potatoes, and grass crops have thus been experimented upon. Incidentally there have been extensive sampling and analysing of soils, investigations into rainfall and the composition of drainage waters, inquiries into the amount of water transpired by plants, and experiments on the assimilation of free nitrogen.

Amongst the field experiments there is, perhaps, not one of more universal interest than that in which wheat has been grown for fifty-seven years in succession, (a) without manure, (b) with farmyard manure, and (c) with various artificial manures. The results show that, unlike leguminous crops such as beans or clover, wheat may be successfully grown for many years in succession on ordinary arable land, provided suitable manures be applied, and the land be kept clean. Even without manure, the average produce over forty-six years, 1852-97, was nearly thirteen bushels per acre, or more than the average yield of the whole of the United States of America, including their rich prairie lands—in fact, about the average yield per acre of the wheat lands of the whole world. Mineral manures alone give very little increase, nitrogenous manures alone considerably more than mineral manures alone, but the mixture of the two considerably more than either separately. In one case, indeed, the average produce by mixed mineral and nitrogenous manure was more than that by the annual application of farmyard manure; and in seven out of the ten cases in which such mixtures were used the average yield per acre was from over two to over eight bushels more than the average yield of the United Kingdom (assuming this to be about twenty-eight bushels of 60 lb per bushel) under ordinary rotation. It is estimated that the reduction in yield of the unmanured plot over the forty years, 1852-91, after the growth of the crops without manure during the eight preceding years, was, provided it had been uniform throughout, equivalent to a decline of one-sixth of a bushel from year to year due to exhaustion—that is, irrespectively of fluctuations due to season. It is related that a visitor from the United States, talking to Sir John Lawes, said, “Americans have learnt more from this field than from any other agricultural experiment in the world.”

Another field experiment of singular interest is that relating to the mixed herbage of permanent meadow, for which seven acres of old grass land were set apart in Rothamsted Park in 1856. Of the twenty plots into which this land is divided, two have been left without manure from the commencement, two received ordinary farmyard manure for a series of years, whilst the remainder have each received a different description of artificial or chemical manure, the same being, except in special cases, applied year after year on the same plot. No one can inspect this field during the growing season without being impressed by the striking evidence it affords of the influ-

ence of different manurial dressings. So much, indeed, does the character of the herbage vary from plot to plot that the effect may fairly be described as kaleidoscopic. Repeated analyses have shown how greatly both the botanical constitution and the chemical composition of the mixed herbage vary according to the description of manure applied. They have further shown how dominant is the influence of season. Such, moreover, is the influence of different manures that the gross produce of the mixed herbage is totally different on the respective plots according to the manure employed, both as to the proportion of the various species composing it, and as to their condition of development and maturity.

The experiments with farm animals began in 1847, and amongst the points that have been investigated are the following:—(1) The amount of food, and of its several constituents, consumed (*a*) in relation to a given live weight of animal within a given time, (*b*) to produce a given amount of increase in live weight. (2) The proportion and relative development of the different organs, or parts, of different animals. (3) The proximate and ultimate composition of the animals in different conditions as to age and fatness, and the probable composition of their increase in live weight during the fattening process. (4) The composition of the solid and liquid excreta (the manure) in relation to that of the food consumed. (5) The loss or expenditure of constituents by respiration and the cutaneous exhalations—that is, in the mere sustenance of the living meat-and-manure-making machine. (6) The yield of milk in relation to the food consumed to produce it; and the influence of different descriptions of food on the quantity and on the composition of the milk.

Incidentally, the results obtained from these inquiries have furnished data essential to the consideration of such problems as (*a*) the sources in the food of the fat produced in the animal body; (*b*) the characteristic demands of the animal body—for nitrogenous or non-nitrogenous constituents of food—in the exercise of muscular power; (*c*) the comparative characters of animal and vegetable food in human dietaries.

In proceeding to discuss the various classes of crops, it will be convenient to deal with them under the three separate heads of root-crops, cereal crops, and leguminous crops, and then to inquire into their inter-relations when grown in rotation.

Root-Crops.—Experiments upon root-crops—chiefly white turnips, Swedish turnips (swedes), and mangels—have resulted in the establishment of the following conclusions. Both the quantity and the quality of the produce, and consequently its feeding value, must depend greatly upon the selection of the best description of roots to be grown, and on the character and the amount of the manures, and especially on the amount of nitrogenous manure employed. At the same time, no hard and fast rules can be laid down concerning these points. Independently of the necessary consideration of the general economy of the farm, the choice must be influenced partly by the character of the soil, but very much more by that of the climate. Judgment founded on knowledge and aided by careful observation, both in the field and in the feeding-shed, must be relied upon as the guide of the practical farmer. Over and above the great advantage arising from the opportunity which the growth of root-crops affords for the cleaning of the land, the benefits of growing the root-crop in rotation are due (1) to the large amount of manure applied for its growth, (2) to the large residue of the manure left in the soil for future crops, (3) to the large amount of matter at once returned as manure again in the leaves, (4) to the large amount of

food produced, and (5) to the small proportion of the most important manurial constituents of the roots which is retained by store or fattening animals consuming them, the rest returning as manure again; though, when roots are consumed for the production of milk, a much larger proportion of the constituents is lost to the manure.

Cereal Crops—Barley and Wheat.—Experiments upon the growth of barley for nearly fifty years in succession on rather heavy ordinary arable soil have resulted in showing that the produce by mineral manures alone is larger than that without manure; that nitrogenous manures alone give more produce than mineral manures alone; and that mixtures of mineral and nitrogenous manure give much more than either used alone—generally twice, or more than twice, as much as mineral manures alone. Of mineral constituents, whether used alone or in mixture with nitrogenous manures, phosphates are much more effective than mixtures of salts of potash, soda, and magnesia. The average results show that, under all conditions of manuring—excepting with farmyard manure—the produce was less over the later than over the earlier periods of the experiments, an effect partly due to the seasons. But the average produce over forty years of continuous growth of barley was, in all cases where nitrogenous and mineral manures (containing phosphates) were used together, much higher than the average produce of the crop grown in ordinary rotation in the United Kingdom, and very much higher than the average in most other countries when so grown. The requirements of barley within the soil, and its susceptibility to the external influences of season, are very similar to those of its near ally, wheat. Nevertheless, there are distinctions of result dependent on differences in the habits of the two plants, and in the conditions of their cultivation accordingly. Wheat is, as a rule, in the British Isles sown in the autumn on a heavier soil, and has four or five months in which to distribute its roots, and so it gets possession of a wide range of soil and subsoil before barley is sown in the spring. Barley, on the other hand, is sown in a lighter surface soil, and, with its short period for root-development, relies in a much greater degree on the stores of plant-food within the surface soil. Accordingly, it is more susceptible to exhaustion of surface soil as to its nitrogenous, and especially as to its mineral supplies; and in the common practice of agriculture it is found to be more benefited by direct mineral manures, especially phosphatic manures, than is wheat when sown under equal soil conditions. The exhaustion of the soil induced by both barley and wheat is, however, characteristically that of available nitrogen; and when, under the ordinary conditions of manuring and cropping, artificial manure is still required, nitrogenous manures are, as a rule, necessary for both crops, and, for the spring-sown barley, superphosphate also. Although barley is appropriately grown on lighter soils than wheat, good crops, of fair quality, may be grown on the heavier soils after another grain crop by the aid of artificial manures, provided that the land is sufficiently clean.

Leguminous Crops and the Acquisition of Nitrogen.—The fact that the growth of a leguminous crop, such as red clover, leaves the soil in a higher condition for the subsequent growth of a grain crop—that, indeed, the growth of such a leguminous crop is to a great extent equivalent to the application of a nitrogenous manure for the cereal crop—was in effect known ages ago. The Romans recognized it two thousand years since, for Varro writes, “Certain things are to be sown, not with the hope of any immediate profit being derived from them, but with a view to the following year, because being ploughed in and then left in the ground, they render the soil after-

wards more fruitful"; and the plants used for this purpose were lupins, beans, vetches, and other leguminous species. Nevertheless, it was not till near the approach of the closing decade of the 19th century that the explanation of this long-established point of agricultural practice was forthcoming. It was in the year 1886 that Hellriegel and Wilfarth first published in Germany the results of investigations in which they demonstrated that through the agency of micro-organisms dwelling in nodular outgrowths on the roots of ordinary leguminous plants the latter are enabled to assimilate the free nitrogen of the air. The existence of the root nodules had long been recognized, but hitherto no adequate explanation had been afforded as to their function.

Since Hellriegel's striking discovery farm crops have been conveniently classified as nitrogen-accumulating and nitrogen-consuming. To the former belong the ordinary leguminous crops—the clovers, beans, peas, vetches or tares, sainfoin, lucerne, for example—which obtain their nitrogen from the air, and are independent of the application of nitrogenous manures, whilst in their roots they accumulate a store of nitrogen which will ultimately become available for future crops of other kinds. It is, in fact, fully established that these leguminous crops acquire a considerable amount of nitrogen by the fixation of the free nitrogen of the atmosphere under the influence of the symbiotic growth of their root-nodule-microbes and the higher plant. The cereal crops (wheat, barley, oats, rye, maize); the cruciferous crops (turnips, cabbage, kale, rape, mustard); the solanaceous crops (potatoes); the chenopodiaceous crops (mangels, sugar beets), and other non-leguminous crops have, so far as is known, no such power, and are therefore more or less benefited by the direct application of nitrogenous manures. The field experiments on leguminous plants at Rothamsted have shown that land which is, so to speak, exhausted so far as the growth of one leguminous crop is concerned, may still grow very luxuriant crops of another plant of the same natural order, but of different habits of growth, and especially of different character and range of roots. This result is doubtless largely dependent on the existence, the distribution, and the condition of the appropriate microbes for the due infection of the different descriptions of plant, for the micro-organism that dwells symbiotically with one species is not identical with that which similarly dwells with another. It seems certain that success in any system involving a more extended growth of leguminous crops in rotations must be dependent on a considerable variation in the description grown. Other essential conditions of success will commonly include the liberal application of potash and phosphatic manures, and sometimes chalking or liming for the leguminous crop. As to how long the leguminous crop should occupy the land, the extent to which it should be consumed on the land, or the manure from its consumption be returned, and under what conditions the whole or part of it should be ploughed in—these are points which must be decided as they arise in practice. It seems obvious that the lighter and poorer soils would benefit more than the heavier or richer soils by the extended growth of leguminous crops.

Remarkable as Hellriegel's discovery was, it merely furnished the explanation of a fact which had been empirically established by the husbandman long before, and had received most intelligent application when the old four-course (or Norfolk) rotation was devised. But it gave some impetus to the practice of green manuring with leguminous crops, which are equally capable with such a crop as mustard of enriching the soil in humus, whilst in addition they bring into the soil from the atmosphere a quantity of nitrogen available for the use of subsequent

crops of any kind. In Canada and the United States this rational employment of a leguminous crop for ploughing in green is being largely resorted to for the amelioration of worn-out wheat lands and other soils, the condition of which has been lowered to an unremunerative level by the repeated growth year after year of a cereal crop. The well-known paper of Lawes, Gilbert, and Pugh (1861), "On the Sources of the Nitrogen of Vegetation, with special Reference to the Question whether Plants assimilate free or uncombined Nitrogen," answered the question referred to in the negative. The attitude now taken up with regard to this problem is set forth in the following words, which are quoted from the Memoranda of the Rothamsted Experiments, 1900 (p. 7):—

Experiments were commenced in 1857, and conducted for several years in succession, to determine whether plants assimilate free or uncombined nitrogen, and also various collateral points. Plants of the gramineous, the leguminous, and of other families, were operated upon. The late Dr Pugh took a prominent part in this inquiry. The conclusion arrived at was that our agricultural plants do not themselves directly assimilate the free nitrogen of the air by their leaves.

In recent years, however, the question has assumed quite a new aspect. It now is—whether the free nitrogen of the atmosphere is brought into combination under the influence of micro-organisms, or other low forms, either within the soil, or in symbiosis with a higher plant, thus serving indirectly as a source of nitrogen to plants of a higher order. Considering that the results of Hellriegel and Wilfarth on this point were, if confirmed, of great significance and importance, it was decided to make experiments at Rothamsted on somewhat similar lines. Accordingly, a preliminary series was undertaken in 1888; more extended series were conducted in 1889 and in 1890; and the investigation was continued up to the commencement of the year 1895. Further experiments relating to certain aspects of the subject were commenced in 1898, and are still in progress. The results have shown that, when a soil growing leguminous plants is infected with appropriate organisms, there is a development of the so-called leguminous nodules on the roots of the plants, and coincidentally, increased growth, and gain of nitrogen.

The Rotation of Crops.—Although many different rotations of crops are practised, they may for the most part be considered as little more than local adaptations of the system of alternating root-crops and leguminous crops with cereal crops, as exemplified in the old four-course rotation—roots, barley, clover, wheat. The rotations extending to five, six, seven, or more years are, in most cases, only adaptations of the principle to variations of soil, altitude, aspect, climate, markets, and other local conditions. They are effected chiefly by some alteration in the description of the root-crop, and perhaps by the introduction of the potato crop; by growing a different cereal, or it may be more than one cereal consecutively; by the growth of some other leguminous crop than clover, or the intermixture of grass seeds with the clover, and perhaps by the extension of the period allotted to this member of the rotation to two or more years. Whatever the specific rotation, there may in practice be deviations from the plan of retaining on the farm the whole of the root-crops, the straw of the grain crops, and the leguminous fodder crops (clover, vetches, sainfoin, &c.), for the production of meat or milk, and, coincidentally, for that of manure to be returned to the land. It is equally true that, when under the influence of special local or other demand—proximity to towns, easy railway or other communication, for example—the products which would otherwise be retained on the farm are exported from it, the import of town or other manures is generally an essential condition of such practice. This system of free sale, indeed, frequently involves full compensation by purchased manures of some kind. Such deviations from the practice of merely selling grain and meat off the farm have much extended in recent years, and will probably continue to do so under the altered conditions of British agriculture, determined

by very large imports of grain, increasing imports of meat and of other products of stock-feeding, and very large imports of cattle-food and other agricultural produce. More attention is thus being devoted to dairy produce, not only on grass farms, but on those that are mainly arable.

The benefits that accrue from the practice of rotation are well illustrated in the results obtained from the investigations at Rothamsted into the simple four-course system, which may fairly be regarded as a self-supporting system. Reference may first be made to the important mineral constituents of different crops of the four-course rotation. Of *phosphoric acid*, the cereal crops take up as much as, or more than, any other crops of the rotation, excepting clover; and the greater portion thus taken up is lost to the farm in the saleable product—the grain. The remainder, that in the straw, as well as that in the roots and the leguminous crops, is supposed to be retained on the farm, excepting the small amount exported in meat and milk. Of *potash*, each of

the rotation crops takes up very much more than of phosphoric acid. But much less potash than phosphoric acid is exported in the cereal grains, much more being retained in the straw, whilst the other products of the rotation—the root and leguminous crops—which are also supposed to be retained on the farm, contain very much more potash than the cereals, and comparatively little of it is exported in meat and milk. Thus, the whole of the crops of rotation take up very much more of potash than of phosphoric acid, whilst probably even less of it is ultimately lost to the land. Of *lime*, very little is taken up by the cereal crops, and by the root-crops much less than of potash; more by the leguminous than by the other crops, and, by the clover especially, sometimes much more than by all the other crops of the rotation put together. Very little of the lime of the crops, however, goes off in the saleable products of the farm in the case of the self-supporting rotation under consideration. Although, therefore, different, and sometimes very large, amounts of these

typical mineral constituents are taken up by the various crops of rotation, there is no material export of any in the saleable products, *excepting of phosphoric acid and of potash*; and, so far at least as phosphoric acid is concerned, experience has shown that it may be advantageously supplied in purchased manures.

Of *nitrogen*, the cereal crops take up and retain much less than any of the crops alternated with them, notwithstanding the circumstance that the cereals are very characteristically benefited by nitrogenous manures. The root-crops, indeed, may contain two, or more, times as much nitrogen as either of the cereals, and the leguminous

crops, especially the clover, much more than the root-crops. The greater part of the nitrogen of the cereals is, however, sold off the farm; but perhaps not more than 10 or 15 per cent. of that of either the root-crop or the clover (or other forage leguminous crop) is sold off in animal increase or in milk. Most of the nitrogen in the straw of the cereals, and a very large proportion of that of the much more highly nitrogen-yielding crops, returns to the land as manure, for the benefit of future cereal and other crops. As to the source of the nitrogen of the root-crops—the so-called “restorative crops”—these are as dependent as any crop that is grown on available nitrogen within the soil, which is generally supplied by the direct application of nitrogenous manures, natural or artificial. Under such conditions of supply, however, the root-crops, gross feeders as they are, and distributing a very large extent of fibrous feeding root within the soil, avail themselves of a much larger quantity of the nitrogen supplied than the cereal crops would do in similar circumstances. This result is partly due to their period of accumulation and growth extending even months after the period of collection by the ripening cereals has terminated, and at the season when nitrification within the soil is most active, and the accumulation of nitrates in it is the greatest. When a full supply of both mineral constituents and nitrogen is at command, these root-crops assimilate a very large amount of carbon from the atmosphere, and produce, besides nitrogenous food materials, a very large amount of the carbohydrate sugar, as respiratory and fat-forming food for the live stock of the farm. The still more highly nitrogenous leguminous crops, although not characteristically benefited by nitrogenous manures, nevertheless contribute much more nitrogen to the total produce of the rotation than any of the other crops comprised in it. It is the leguminous fodder crops—especially clover, which has a much more extended period of growth, and much wider range of collection within the soil and subsoil, than any of the other crops of the rotation—that yield in their produce the largest amount of nitrogen per acre. Much of this is doubtless taken up as nitrate, yet the direct application of nitrate of soda has comparatively little beneficial influence on their growth. The nitric acid is most likely taken up chiefly as nitrate of lime, but probably as nitrate of potash also, and it is significant that the high nitrogen-yielding clover takes up, or at least retains, very little soda. Table XXIX. from Warington's *Chemistry of the Farm* will serve to illustrate the subjects that have been discussed in this section.

It is not only the conditions of growth, but the *uses* to which the different crops are put, that have to be considered in the case of rotation. Thus the cereal crops, when grown in rotation, yield more produce for sale in the season of growth than when grown continuously. Moreover, the crops alternated with the cereals accumulate very much more of mineral constituents and of nitrogen in their produce than do the cereals themselves. By far the greater proportion of those constituents remains in circulation in the manure of the farm, whilst the remainder yields highly valuable products for sale in the forms of meat and milk. With a variety of crops, again, the mechanical operations of the farm, involving horse and hand labour, are better distributed over the year, and are therefore more economically performed. The opportunities which rotation cropping affords for the cleaning of the land from weeds is another distinct element of advantage.

THE FEEDING OF ANIMALS, AND THE MANURIAL VALUE OF DIFFERENT FOODS.

In the feeding experiments at Rothamsted it has been shown that the amount of food consumed, both for a given

live weight of animal within a given time, and for the production of a given amount of increase, is, as current food-stuffs go, measurable more by the amounts they contain of digestible and available non-nitrogenous constituents than by the amounts of the digestible and available nitrogenous constituents they supply. The non-nitrogenous substance (the fat) in the increase in live weight of an animal is, at any rate in great part, if not entirely, derived from the non-nitrogenous constituents of the food. Of the nitrogenous compounds in food, on the other hand, only a small proportion of the whole consumed is finally stored up in the increase of the animal—in other words, a very large amount of nitrogen passes through the body beyond that which is finally retained in the increase, and so remains for manure. Hence it is that the amount of food consumed to produce a given amount of increase in live weight, as well as that required for the sustentation of a given live weight for a given time, should—provided the food be not abnormally deficient in nitrogenous substance—be characteristically dependent on its supplies of digestible and available non-nitrogenous constituents. It has further been shown that, in the exercise of force by animals, there is a greatly increased expenditure of the non-nitrogenous constituents of food, but little, if any, of the nitrogenous. Thus, then, alike for maintenance, for increase, and for the exercise of force, the exigencies of the system are characterized more by the demand for the digestible non-nitrogenous or more specially respiratory and fat-forming constituents than by that for the nitrogenous or more specially flesh-forming ones: Hence, as current fattening food-stuffs go—assuming, of course, that they are not abnormally low in the nitrogenous constituents—they are, *as foods*, more valuable in proportion to their richness in digestible and available non-nitrogenous than to that of their nitrogenous constituents. As, however, the manure of the animals of the farm is valuable largely in proportion to the nitrogen it contains, there is, so far, an advantage in giving a food somewhat rich in nitrogen, provided it is in other respects a good one, and, weight for weight, not much more costly.

In Table XXX., which underwent revision in 1885, and was adopted as trustworthy in 1897, is shown the average composition, both per cent. and per ton, of all the leading cattle-foods. It is obvious that, in the case of almost every one of the articles enumerated, individual samples may vary even considerably from the average. In foods which are manufactured or imported the percentage of dry matter is usually high. In those which may be either imported or home-grown, the variations in the percentage of dry matter in different samples may be comparatively wide, it being as a rule distinctly higher in the imported articles, which could not be shipped unless in a drier condition than is usual with the home-grown product. In such cases the imported food will probably contain a higher, or the home-grown one a lower, percentage of dry matter than the average given in the table. Hence the figures as tabulated need to be adopted or modified with judgment, having regard to the influence of the conditions of growth, maturity, preparation, or preservation to which the foods have been subject. Unless, however, the variation from the standard composition adopted in the table be more than usual, the effect on the estimates of the manure value—for which the table is primarily intended—will not be material, though it will obviously be much greater in the case of the nitrogen than in that of either the phosphoric acid or the potash. The table is useful for purposes of comparison—for example, one ton of decorticated cotton cake contains about four times as much nitrogen as a ton of maize, wheat, or barley, and thirty times as much as a ton of mangel wurzels.

36. White turnips	8·00	0·18	0·68	0·05	0·30	4·03	1·12	6·72

¹ In the case of neither rice meal, locust beans, nor yellow turnips, have records of ash analyses been found. For rice meal the same percentages of phosphoric acid and potash as in maize, and for yellow turnips the same as in swedes, are provisionally adopted; but where the results are assumed they are given in parentheses. For locust beans no figure has been assumed and the columns are left blank.

Table XXXI, revised by Lawes and Gilbert in 1897, shows the method and the results of the calculation of the total or original manure value of the different foods, adopting as a basis their composition as given in Table XXX. When the table was constructed in 1875 the values per lb of the important manurial ingredients were taken as ammonia, 8d.; phosphoric acid, 2½d.; potash, 2d. At the revision of the table in 1885 these were altered to 6d., 3d., and 2½d. respectively. At the subsequent revision in 1897 the fluctuations in prices which had then taken place rendered necessary a further modification to 4d. per lb for ammonia, 2d. per lb for phosphoric acid, and 1½d. per lb for potash, these being the lowest of all. They determine the figures given in the last column of the table, representing the total manure value per ton of food consumed. The sum of £2, 11s. 11d., for example, denoting the manure value of one ton of linseed cake consumed, is the aggregate of £2, 1s. 2d. for nitrogen; 6s. 11d. for phosphoric acid, and 3s. 10d. for potash.

This table is of interest alike to the stockfeeder and to the valuer, and it will repay closer study. The first column shows the estimated amounts of each food required to give one part of fattening increase in live

weight of oxen or sheep; and the second column shows the amounts of such increase that would, accordingly, be acquired by the consumption of one ton of each food. Some such estimate must necessarily be made before it is possible to calculate how much of the manure constituents of the food are carried off by the animal increase, and consequently how much remain for manure. It must not, however, be concluded that, by the consumption by oxen or sheep of one ton of any one of the different foods used alone, the amount of fattening increase given in the second column of the table would be produced,—that, for example, a ton of linseed cake, if so given, would yield 373 lb, a ton of oat straw 124 lb, or a ton of mangels 23 lb of increase. What is meant is that, when any one of the foods is given in the judicious amount and in admixture with other foods which experience shows to be beneficial, it may be estimated that one ton of the food so consumed will, approximately, contribute the amount of increase in live weight stated.

Taking into consideration the difficulties attending the experimental determination of these values, it is claimed that they are the best that existing knowledge renders it possible to arrive at. Nevertheless, it is pretty certain

TABLE XXXI.—Showing the Data, the Method, and the Results of the Estimation of the Original Manure Value of Cattle Foods after Consumption.

NOTE.—Assumed results are given in parentheses.

that the amounts of increase assumed to be produced are higher than those usually obtained. The amount estimated to be yielded by linseed cake, for example, is certainly higher than would be obtained when, as is sometimes the case, it is given in such excessive amount that much is voided by the animals undigested. On the other hand, the amounts of the different foods estimated to be required to give one part of increase are doubtless higher than would be so required, if as large a proportion of the constituents were digested and utilized as has been shown to be digestible in the German experiments on that subject. In those experiments the animals were for the most part kept on mere sustenance food, so that they would digest the maximum proportion of the constituents they received. In the case of fattening, however, especially with early maturity, the conditions are very different. The animal receives a greater or less excess of food, and not only voids proportionally more undigested, but may transform more than is fully utilized. It is, nevertheless, economy to give an excess within certain limits. The apparent waste is, in fact, more than counterbalanced. Thus, in the first place, the manure value of the not-utilized food still remains intact; but the real source of the economy is in the shortening of the time of feeding, and so, at the cost of some excess of food, saving the amount that would be expended in the mere sustenance of the animal in feeding for a longer period.

The next section of the table, headed "Nitrogen," and comprising seven columns, relates to the amount and to the distribution of the foods. There are given the amounts of nitrogen per cent. and per ton as in Table XXX.; the actual amount estimated to be contained in the increase in live weight of the animal consuming one ton of the food, and the percentage of the total nitrogen consumed which is so retained in the increase; the amount of the nitrogen of the food remaining for manure, the amount of ammonia to which it corresponds, and its money value, reckoned at 4d. per lb. Throughout the calculations it is assumed that only fattening increase is produced, and that this will contain 8 per cent. of nitrogenous substance, corresponding to 1.27 per cent. of nitrogen in the increase. It will be seen that, according to the figures, the only food in the list of which a ton is estimated to contribute more than 5 lb of nitrogen to the fattening increase is linseed, and that in the case of none of the cakes, or of the leguminous seeds, will 1 ton contribute 5 lb of nitrogen to the increase, whilst the amount is in several cases under 4 lb. A ton of the cereal grains, or of their products (and locust beans), generally contributes under 4 lb; a ton of hay or straw less than half as much; and a ton of roots very much less still. To put it in another way: of the total nitrogen consumed in the foods rich in that substance, such as the cakes and the leguminous seeds, there is generally less than 5 per cent. retained in the fattening increase in live weight. The cereal grains, on the other hand, which are much less rich in nitrogen, contribute a much larger proportion of their total amount to the increase; indeed, generally about 10 per cent. of it. The gramineous straws contribute a higher proportion still, whilst roots (mangels and turnips) lose by feeding on an average only about 5 or 6 per cent. of their nitrogen. Hence, when fattening increase only is produced, the proportion of the nitrogen of the food which is retained by the animal, and so lost to the manure, is very small in the case of the richer foods, but more in that of the poorer ones; but even with them it seldom exceeds 10 per cent., excepting with the straws. It may be assumed, however, that when the foods are consumed by store animals, about twice as much of the nitrogen of the food is retained by the animal, and

so lost to the manure. And when, as is more and more the case with early maturity, the increase comprises a larger proportion of growth than in mere fattening, the amount of the nitrogen of the food which will be lost to the manure will be between that given in the table and twice as much.

The third section of the table relates to the phosphoric acid, and there are given for each food, as in the case of the nitrogen, the amounts of it per cent. and per ton of the foods; the amount estimated to be retained in the increase; the amount remaining for manure, and the money value of this at 2d. per lb. It will be seen that there is only about two-thirds as much phosphoric acid as of nitrogen retained in a given weight of fattening increase; but, owing to the very generally less, and sometimes much less, amount of it in the foods, a greater proportion of that consumed is retained in the animal, and a less proportion remains for manure. It should be added that, in the case of store animals and of animals still growing, the amount of phosphoric acid retained in a given weight of increase will be very much greater than in mere fattening; indeed, in mere store increase it may, as in the case of the nitrogen, be nearly twice as great.

Of potash, the table shows that a given weight of fattening increase retains only about one-eighth as much as it does of phosphoric acid; and the percentage of the whole in the food which is lost to the manure is generally very small. In its case, as in that of the nitrogen and phosphoric acid, the amount retained in mere store increase will be nearly twice as much as in mere fattening increase, but the total quantity retained is still very small. The potash remaining for manure is valued at 1½d. per lb.

The last column of the table shows the total manure value of a ton of each of the foods after consumption, reckoning the nitrogen, the phosphoric acid, and the potash at the prices above named, which are those at which they could, at the time (1897-98), be purchased in artificial manures. The reductions in the prices of ammonia, phosphoric acid, and potash, now adopted, bring all the estimates of total or original manure value almost exactly one-third lower than those given in 1885. Thus the total value of a ton of linseed cake consumed, which in 1885 was reckoned at £3, 18s. 6d., was taken in 1897-98 at £2, 11s. 11d.; that of a ton of oats was reduced from £1, 9s. 10d. to 19s. 9d.; and that of other foods in the same proportion.

Unexhausted Manure Value of Cattle Foods.—A much more complicated problem than the estimation of the total or original manure value of cattle foods is that of estimating the *unexhausted manure value* of the different foods, or what may be called their *compensation value*, after they have been used for a series of years by the outgoing tenant, and he has realized a certain portion of the manure value in his increased crops. In the light of experimental and other evidence, Lawes and Gilbert fixed upon a scale of reduction, starting from the total or original manure value, as estimated in Table XXXI. The method so arrived at is to deduct one-half of the original manure value of the food used the last year, and one-third of the remainder each year to the eighth, in the case of all the more concentrated foods, and of the roots; whilst, for the hays and straws, which contain larger amounts of indigestible matter, and the constituents of which will be more slowly available for crops, two-thirds of the original manure value is deducted for the last year, and only one-fifth from year to year to the eighth year. The results of the estimates of *compensation value* so made are given in Table XXXII. The first column shows the total or original manure value of each food. The second column shows the allowance

TABLE XXXII.—*Plan and Results of Estimations of the Compensation Value of Unexhausted Manure, starting from the Original Manure Value, that is, the Value deducting the constituents of increase in (Fattening) Live Weight only.*

for the last year, and the succeeding seven columns that for each succeeding year to the eighth. The last column gives the *total compensation value* for the eight years' consumption. It may seem at first sight that a deduction of 50 per cent. from the original manure value of the food used in the last year is large. Allowance has to be made, however, for all losses to which the manure may be subject, which may be considerable, especially if much of the food is consumed in the yards; and it has to be borne in mind that the money paid for compensation will not yield its full return for a long time. Only half the original manure value would, therefore, be allowed if the food were only used one year; and all scales of allowance arranged by farmers' clubs assume the consumption for more than one year. Nevertheless, if the food is used for eight years, or more, it will be seen that the total allowance considerably exceeds the original manure value of one year's consumption—the allowance made for the accumulation bringing it up to from one and a third to one and a half as much as the original manure value.

In order to test the applicability of the scale of compensation proposed, the case may be considered of a Norfolk

or Lincolnshire farm under the ordinary four-course rotation, with meat and grain only sold, and the roots fed partly on the land and partly in the yards. Let it be assumed, further, that the land is thoroughly clean, and that the farm is in every respect in good order when given up. The essential basis of the system of estimate and valuation of the unexhausted residue adopted is the assumption of gradual accumulation within the soil, and of slow recovery from it. Suppose then that linseed cake had been used annually for eight years, at the average rate of one ton over eight acres each year, or of one ton per acre in eight years. Each acre would thus on the average receive, either in farmyard manure or directly by the feeding with roots or clover on the land, the manure from the consumption of one ton of linseed cake in eight years, or at the average rate of one-eighth of a ton, or $2\frac{1}{2}$ cwt., per acre per annum.

The first column of Table XXXII. shows that the *total or original manure value* of one ton of linseed cake consumed—that is, the value deducting only the constituents stored up in the animal—is estimated to be £2, 11s. 11d. The subsequent columns of the same table show the estimated *compensation value* of the *unexhausted residue*

from one ton consumed (that is, after the tenant has realized the benefit of the increase of his crops) to be, if used each year for eight years, as given in the first column of the following statement, the second column showing the amount per acre per annum:—

	Compensation Allowances for One Ton of Linseed Cake consumed.	
	Per annum, Eight Years.	Per acre, in Eight Years.
Last year	£ s. d. 1 6 0	£ s. d. 0 3 3
2nd "	0 17 4	0 2 2
3rd "	0 11 7	0 1 5
4th "	0 7 9	0 1 0
5th "	0 5 2	0 0 8
6th "	0 3 5	0 0 5
7th "	0 2 3	0 0 3
8th "	0 1 6	0 0 2
Total	3 15 0	0 9 4

Thus, according to the first column of figures, the value of the unexhausted manure residue from the consumption of one ton of linseed cake annually for eight years would be £3, 15s., or nearly 45 per cent. more than the original manure value of one year's consumption. Or, as the second column shows, the allowance would be at the rate of 9s. 4d. per acre over the whole farm. Whether such an allowance would be too much or too little under the conditions supposed is a question for consideration. These conditions are: a light-land farm, upon which the manure from purchased food is an essential element of profitable cultivation; that meat and grain alone are sold; and that the farm is given up in a satisfactory state in every respect. Also that, on the average, each acre received during the last eight years the manure derived from the consumption of one ton of linseed cake. The question between the two parties concerned is, whether the outgoing tenant would receive sufficient remuneration for his unexhausted manure; and, on the other hand, whether the landowner, or the incoming tenant, would pay more than will be recovered in increase of crops. An allowance of 9s. 4d. per acre on a farm of 400 acres would amount to £186, 13s. 4d., which is a large sum to pay; and it is certain that the recovery of the amount would only be gradual. It is well known that both time and money are required to get land into condition, and here is land already in condition.

Although in the foregoing tables the estimates of the manure values of food-stuffs are made in accordance with the prices of ammonia, phosphoric acid, and potash at the time (1898), it is evident that the results may require further revision as the value of manure constituents in the market changes, and perhaps also in other ways, as knowledge advances and experience is gained.¹

¹ For a fuller discussion of the subject the reader should consult Lawes and Gilbert's paper in the *Journal of the Royal Agricultural Society*, 1897. In the course of a letter written early in 1901, Sir J. Henry Gilbert referred to the question as to how the manure from store stock should be valued. The loss to the manure is more in the case of the feeding of lean or store stock than in that of fattening animals, but is much less than in the case of milk production. Assuming the increase from the consumption of a given food by store stock removed twice as much of the constituents valuable as manure as when used for fattening, the result would approximately be that, in the case of any of the high-nitrogen foods, Nos. 1 to 11 in Table XXXII., 5 per cent. would be sufficient to deduct from the original manure value before applying the scale according to the "class of farm" as defined below; and that in the case of the lower-nitrogen foods, Nos. 12 to 17, a deduction of 10 per cent. would be sufficient. With reference to the valuation of the manure constituents when the foods are consumed by fattening pigs, the conclusion arrived at is that, although there are characteristic differences between the amount and proportion of the various foods consumed by oxen and sheep on the one hand, and by pigs on the other, yet there would not be such material

IMPLEMENTS AND MACHINERY.

Agricultural machinery is dealt with elsewhere. As, however, it is the custom of the Royal Agricultural Society of England to invite competitions at its annual shows in specified classes of implements, an enumeration of these will indicate the character of the appliances which were thus brought into prominence during the closing quarter of the 19th century. These trials taking place, with few intermissions, year after year serve to direct the public mind to the development, which is continually in progress, of the mechanical aids to agriculture. The awards here summarized are quite distinct from those of silver medals which are given by the Society in the case of articles possessing sufficient merit, which are entered as "new implements for agricultural or estate purposes."

In 1875, at Taunton, special prizes were awarded for one-horse and two-horse mowing machines, hay-making machines, horse rakes (self-acting and not self-acting), guards to the drums of threshing-machines, and combined guards and feeders to the drums of threshing-machines. In 1876, at Birmingham, the competitions were of self-delivery reapers, one-horse reapers, and combined mowers and reapers without self-delivery. In 1878, at Bristol, the special awards were all for dairy appliances—milk-can for conveying milk long distances, churn for milk, churn for cream, butter-worker for large dairies, butter-worker for small dairies, cheese tub, curd knife, curd mill, cheese-turning apparatus, automatic means of preventing rising of cream, milk-cooler, and cooling vat. A gold medal was awarded for a harvester and self-binder (M'Cormick's). In 1879, at Kilburn, the competition was of railway waggons to convey perishable goods long distances at low temperatures. In 1880, at Carlisle, and in 1881, at Derby, the special awards were for broadside steam diggers and string sheaf-binders respectively. In 1882, at Reading, a gold medal was given for a cream separator for horse power, whilst a prize of 100 guineas offered for the most efficient and most economical method of drying hay or corn crops artificially, either before or after being stacked, was not awarded. In 1883, at York, a prize of £50 was given for a butter dairy suitable for not more than twenty cows. In 1884, at Shrewsbury, a prize of £100 was awarded for a sheaf-binding reaper, and one of £50 for a similar machine. In 1885, at Preston, the competitions were concerned with two-horse, three-horse, and four-horse whittle-trees, and packages for conveying fresh butter by rail. In 1886, at Norwich, a prize of £25 was awarded for a thatch-making machine. In 1887, at Newcastle-on-Tyne, a prize of £200 went to a compound portable agricultural engine, one of £100 to a simple portable agricultural engine, and lesser prizes to a weighing machine for horses and cattle, a weighing machine for sheep and pigs, potato-raisers, and one-man power cream separators. In 1888, at Nottingham, hay and straw presses for steam power, horse power, and hand power were the subjects of competition. In 1889, at Windsor, prizes were awarded for a fruit and vegetable evaporator, a paring and coring machine, a dairy thermometer, parcel post butter-boxes to carry different weights, and a vessel to contain preserved butter. In 1890, at Plymouth, competitions took place of light portable engines (a) using solid fuel (b) using liquid or gaseous fuel, grist mills for use on a farm, disintegrators, and cider-making plant for use on a farm. In 1891, at Doncaster, special prizes were given for combined portable threshing and finishing machines, and cream separators (hand and power). In 1892, at Warwick, the competitions related to ploughs—single furrow (a) for light land, (b) for strong land, (c) for press drill and broadcast sowing; two-furrow; three-furrow; digging (a) for light land (b) for heavy land; and one-way ploughs. In 1893, at Chester, self-binding harvesters and sheep-shearing machines (power) were the appliances respectively in competition. In 1894, at Cambridge, the awards were for fixed and portable oil engines, potato-spraying and tree-spraying machines, sheep-dipping apparatus, and churns. In 1895, at Darlington, the competitions were confined to hay-making machines and clover-making machines. In 1896, at

difference in the case of the same description of food consumed respectively by oxen, sheep, and pigs, as to render it desirable to make any distinction in estimating the manure value of the same food thus consumed.

In actual practice it has been found convenient, in applying the estimates of manure value, to modify the compensation according to the class of farm, thus: (1) where the consumption is on farms that have been well managed, with the yard accommodation for the proper conservation of manure good, or where the feeding-stuffs have been fed on land left clean, and the management has been generally good and judicious; (2) where such conditions are not so good and meritorious; (3) where such conditions are bad.

Leicester, prizes were awarded after trial to potato-planting machines, potato-raising machines, and butter-drying machines. In 1897, at Manchester, special awards were made for fruit baskets and milk-testers. In 1898, at Birmingham, a prize of £100 was given for a self-moving vehicle for light loads, £100 and £50 for self-moving vehicles for heavy loads, and £10 for safety feeder to chaff-cutter, in accordance with the Chaff-cutting Machines (Accidents) Act, 1897. In 1899, at Maidstone, special prizes were offered for machines for washing hops with liquid insecticides, cream separators (power and hand), machines for the evaporation of fruit and vegetables, and packages for the carriage of (a) soft fruit, (b) hard fruit. In 1900, at York, the competitions were concerned with horse-power cultivators, self-moving steam diggers, milking machines, and sheep-shearing machines (power and hand). In 1901, at Cardiff, competition was invited in portable oil engines, agricultural locomotive oil engines, and small ice-making plant suitable for a dairy.

The progress of steam cultivation has not justified the hopes that were once entertained concerning this method of working implements in the field. It was about the year 1870 that its advantages first came into prominent notice. At that time owing to labour disputes the supply of hands was short and horses were dear. The wet seasons that set in at the end of the 'seventies led to so much hindrance in the work on the land that the aid of steam was further called for, and it seemed probable that there would be a lessened demand for horse power. It was found, however, that the steam work was done with less care than had been bestowed upon the horse tillage, and the result was that steam came to be regarded as an auxiliary to horse labour rather than as a substitute for it. In this capacity it is capable of rendering most valuable assistance, for it can be utilized in moving extensive areas of land in a very short time. Accordingly, when a few days occur early in the season favourable to the working of the land, much of it can be got into a forward condition, whilst horses are set free for the lighter operations. The crops can then be sown in due time, which in wet years, and with the usual teams of horses kept on a farm, is not always practicable. Much advantage arises from the steam-working of bastard fallows in summer, and after harvest a considerable amount of autumn cultivation can be done by steam power, thus materially lightening the work in the succeeding spring. On farms of moderate size it is usual to hire steam tackle as required, the outlay involved in the purchase of a set being justifiable only in the case of estates or of very big farms where, when not engaged in ploughing, or in cultivating, or in other work upon the land, the steam-engine may be employed in threshing, chaff-cutting, sawing, and many similar operations which require power. The labour question again became acute in 1900, when owing to the scarcity of hands and the high rate of wages, self-binding harvesters were resorted to in England for the ingathering of the corn crops to a greater extent than ever before. For the same reason potato-planting and potato-lifting machines were also in greater requisition. (W. FR.)

II. THE UNITED STATES.

Covering as it does the breadth of the North American continent, with 3,000,000 square miles of land surface, not including Alaska and the islands, of which 700,000,000 acres are in farms and 400,000,000 in actual cultivation, representing every variety of soil and all the climatic life zones of the world, except the extreme boreal and the hottest tropical, the United States affords an important subject of study in respect of agriculture. Its cotton, wheat, and meat are large factors in all markets, and its many other agricultural products are distributed throughout the civilized world. To the student the equipment and methods of agriculture in the United States form as interesting a subject of examination as do its resources and production. In quantity, distribution,

and inter-relation of heat and moisture—the chief factors in agricultural production—the United States is greatly blessed. We find in this vast territory all the agricultural belts mapped by the biologist, producing all varieties of cereals, fruits, and breeds of live stock. All kinds of soils, adapted to different crops, are spread out at all altitudes from 8000 feet down to sea-level. The country is equally fortunate in the character of its farming class. There is no peasant class, but the agricultural population is made up of the same people who form the professional and mercantile classes. The negroes, who supply the farm labour in the Southern States, are by nature admirably suited to these pursuits. The inventive skill of the American has had almost as full scope upon the farm as in the shop, with the result that the equipment and methods used are well adapted to the conditions.

The story of the vast and varied agriculture of the United States can be most briefly, and, perhaps, best told in the figures of the census and other Government reports. Unless some other source is mentioned, the statistics in this article are taken from the eleventh (1890) census (crops of 1889), or the reports of the Department of Agriculture, whose annual estimates are based upon the latest figures. *Statistics.*

As a result of the great supply of available land the number of farms in the United States increased between 1850 and 1890 215 per cent., or from 1,450,000 to 4,565,000; their total acreage increased 112 per cent., or from 294,000,000 to 623,000,000 acres; their improved acreage increased 216 per cent., or from 113,000,000 to 358,000,000 acres; and their unimproved acreage 47 per cent., or from 181,000,000 to 266,000,000 acres. The following table (No. I.) exhibits the increases of number of farms, total and improved acreage, by decades:— *Farms.*

TABLE I.—Percentage of Increase of Number and Acreage of Farms by Census Decades.

The United States.	Number of Farms.	Acreage.	
		Total.	Improved.
1850 to 1860	41.1	38.7	44.3
1860 to 1870	30.1	0.1	15.8
1870 to 1880	50.7	31.5	50.7
1880 to 1890	13.9	16.2	25.6
1850 to 1890	215.0	112.3	216.4

The largest percentage of increase of improved land was 5.07, from 1870 to 1880; the lowest was in the decade 1860 to 1870, the period of the Civil war, and was 15.8. There was a marked slackening in the increase both of the number of farms and of improved land in the last decade, when public lands adapted to agriculture had approached more nearly the point of complete occupation. The chief cause of this wonderful development of agriculture is the large area of cheap public lands which has been available for immigrants and natives alike. Up to 1897, 529,000 homestead entries had been made and finally settled for 70,397,000 acres of Government land under the Homestead Act of 20th May 1862, while the number of entries, both final and pending, covered 102,280,000 acres. Between 1875 and 1897 the public and Indian lands sold for cash and under homestead and timber culture laws, as well as those allotted by scrip, granted to the colleges of agriculture and mechanic arts and other institutions, and by military bounty land warrants, and selected by States and railroad corporations, covered 300,000,000 acres. In addition to this, the States and railroad corporations sold a large amount of land to farmers of which we have no accurate record. This vast territory, greater in extent than

Germany and France combined, was added to the farms of the country in twenty-two years. In many cases railroad building has made the settlement of the public lands possible for the first time, and the building of branch lines, by providing means for transporting products to market, has greatly facilitated the acquisition of other lands. The mileage of railways increased 245 per cent. between 1870 and 1896. The interesting fact is that this increase corresponds geographically to the increase in farms.

The agricultural statistics do not include any farm of less than three acres unless it produced at least \$500 worth of products the preceding year. The census of 1890 showed that the average size of farms was 137 acres, or three acres more than in 1880 and 66 acres less than in 1850. Within a certain limit the average area of farms is determined by the financial ability of the owners. In this day of farm machines, an owner must have a certain amount of land in order to afford the necessary equipment for cultivating it successfully. This fact appears to have stopped the further subdivision of farms and to have started a movement towards their consolidation. As will be seen from the following table (No. II.), the average farm, which steadily diminished in size from 1850 to 1880, actually increased slightly between 1880 and 1890, owing chiefly to the enlargement of the wheat farms of the west.

TABLE II.—Average Acreage of Farms and Improved Land therein by Census Years.

The United States.	Average Number of Acres.	
	Improved.	Whole Farm.
1850	78	203
1860	80	198
1870	71	155
1880	70	133
1890	78	137

The figures for the average farm areas of improved land represent more truly the actual economic condition. Thus it is instructive to notice that the number of acres under cultivation (improved land) on each farm was on the average the same—78 acres—at the end of the forty-years period as at its beginning. The existence of available surplus land has its influence; but the increasing use of improved machines and tools, and the construction of convenient railroads, appear to be the chief causes for the enlargement of farms.

In farms cultivated by owners there was an increase between 1880 and 1890 of 285,422, or 9.56 per cent.; in farms rented for money, of 132,302, or 41 per cent.; and in farms rented for a share of the products, of 138,010, or 19.65 per cent. In 1890, 71.6 of all the farms were cultivated by their owners, as against 74.4 per cent. in 1880. From 1880 to 1890 the farm tenancy grew from 25.6 to 28.4 per cent., an increase of 2.8 per cent. The steady drift towards farm tenancy of late is believed to be injurious to production; but it is impossible to prove this, so great has been the aggregate increase in products.

The number of persons engaged in agriculture as a business in 1890 was 8,395,634, or 37 per cent. of all persons in gainful occupations. It is interesting to note that 678,000 of these were women. This is an increase of nearly 1,000,000 persons over 1880, or 12.6 per cent. Thus, if the farm family is the same size as that of the remainder of the population—it is probably slightly larger—the agricultural population would be 37 per cent. of the whole. Statis-

ticians usually put it at 40 per cent., and this is probably more nearly correct.

TABLE III.—Number of Persons of Ten Years of Age and over in the Different Agricultural Pursuits in 1890.

Occupation.	Total Persons.
Dairymen and women	17,895
Farmers and farm superintendents	5,281,557
Farm labourers	3,004,061
Gardeners, nurserymen, and viticulturists	72,601
Other pursuits	19,520
Total	8,395,634

The increase in farm tenancy, and especially the diminished demand for labour relative to products, due to the growing use of machinery, reduced the number of agricultural labourers who work for wages from 49 per cent. of all agricultural workers in 1870 to 43.6 in 1880 and 35.8 in 1890. The wages paid farm labourers, as ascertained by the Department of Agriculture, are rather low compared with the average wages of labour, but not lower than the wages of other unskilled labour. The average monthly wage of the agricultural labourer, without board, was \$19.50 in 1870, \$16.42 in 1880, \$18.33 in 1890, and \$17.70 in 1895. These wages are good as compared with those earned in Continental countries.

The figures for farm capital and the value of agricultural products are so vast that it is extremely difficult to put them in form to be grasped intelligently.

The farm capital of the United States reported by the census of 1890 reached \$15,500,000,000, the main classes being, in round numbers:—

Land, fences, and buildings, \$13,000,000,000; machines and implements, \$500,000,000; live stock, \$2,000,000,000. The products of the farms in the census year, 1889, were valued at \$2,500,000,000. Between 1850 and 1890 the aggregate farm capital increased 303 per cent.; the value of annual products increased between 1870 and 1890, 15.5 per cent. The greatest increase of farm capital was between 1850 and 1860, 101 per cent.; the next was the decade 1880 to 1890, when the increase was 29 per cent. From 1870 to 1880 the value of farm products increased 4 per cent.; from 1880 to 1890, 11 per cent. It is noteworthy that "the value of capital increased in a much greater degree than the value of products."

In order to put the facts about the crops grown in the United States in a form that may be readily understood, Mr Holmes of the Department of Agriculture has computed the number of railroad freight cars of fifteen tons' capacity required to haul the crops of 1897 and what their length in trains would be. He tells us that to haul the hay crop 4,017,933 cars would be needed, and the length of the train would be 25,112 miles, or more than long enough to encircle the earth at the equator; for the corn crop there must be 3,540,257 cars, making a train 22,127 miles long; the wheat crop would take 1,060,000 cars, with a total length of 6625 miles, or farther than from New York to Cape Horn; for the oat crop a train of 772,098 cars, extending 4826 miles, or from New York to the Congo river; the potato crop would take a train of 327,354 cars, and 2046 miles long, which would extend from New York to Utah; the cotton crop would take a train as long as from New York to Chicago, and the barley crop one that would reach from Washington, D.C., to Atlanta, Ga.

The growth of farm area and of capital invested in agriculture was followed by a proportionate increase in the principal crops. Between 1880 and 1890 the area devoted to each crop increased as follows:—Indian corn (maize), 15.6 per cent.; rye, 17.9 per cent.; oats, 75.4 per cent.; barley, 61.2 per cent.; cotton, 39.3 per cent.; sugar-cane, 20.7 per cent.; hay, 72.9 per cent.; and tobacco, 8.8 per cent.; while the area in wheat decreased 5.2 per cent.; buckwheat, 1.3 per cent.; and rice, 7.4 per cent. The

following table (No. IV.), arranged by Holmes, gives the increase or decrease in five principal crops for each decade from 1840, when the first census of agricultural products was taken, down to 1890:—

TABLE IV.—Percentage of Increase (+) or Decrease (–) of Production of Farm Crops, by Time Periods.

The United States.	Indian Corn.	Wheat.	Oats.	Cotton.	Tobacco.
1840 to 1850	+ 58·8	+18·5	+ 19·1	+ 56·2	– 8·9
1850 to 1860	+ 41·7	+72·3	+ 17·8	+118·2	+117·4
1860 to 1870	– 9·3	+66·2	+ 63·4	– 44·1	– 39·5
1870 to 1880	+130·6	+59·7	+ 44·6	+ 91·1	+ 79·9
1880 to 1890	+ 21·0	+ 1·9	+ 98·4	+ 29·8	+ 3·3
1840 to 1890	+462·2	+452·2	+557·6	+372·7	+122·8

The distinguishing feature of the period 1870 to 1880 is the rate of increase of corn, wheat, cotton, and tobacco. Since 1870 the production of nearly all of the farm crops increased more rapidly than the population, the most absolute proof of the substantial prosperity of the people. The increase in population for the fifty years from 1840 to 1890 was 267 per cent.; from 1870 to 1880, 30 per

cent.; from 1880 to 1890, 25 per cent.; but the food and other supplies have far exceeded the demands of even this great population.

Until the use of more and cheaper motors becomes possible, farm animals must increase with farming operations. "At the census of 1890 there were 14,969,467 horses on farms, 2,295,532 mules and asses, 1,117,494 working oxen, 16,511,950 milch cows, 33,734,128 other cattle, 57,409,583 swine, and 35,935,364 sheep, not including spring lambs; and in the census year the wool clip amounted to 165,449,239 pounds, not including pulled wool and wool clipped on ranges, which were sufficient, according to the estimates of the department, to make the entire wool clip for the census year 276,000,000 pounds. In forty years, from the census of 1850 to that of 1890, the number of horses on farms increased 245·2 per cent.; mules and asses, 310·4 per cent.; milch cows, 158·6 per cent.; other cattle, 248 per cent.; swine, 89·1 per cent.; sheep, not including spring lambs, 65·4 per cent., and the farm wool clip increased 215 per cent.; but working oxen decreased 34·3 per cent." (Holmes).

The following tables give the most important facts with regard to the cereal production of the United States between 1870 and 1899 (Tables V. and VI.):—

TABLE V.—Average Yield and Value of Cereal Crops in the United States, by Periods of Years, 1870 to 1899.

The United States.	Corn.			Wheat.			Oats.		
	Average Farm Price per Bushel.	Average Yield per Acre.	Average Value per Acre.	Average Farm Price per Bushel.	Average Yield per Acre.	Average Value per Acre.	Average Farm Price per Bushel.	Average Yield per Acre.	Average Value per Acre.

1870 to 1880 .	0·738	22·1	16·34	0·701	14·1	9·92	0·715	17·7	12·65
1880 to 1889 .	·589	21·7	12·79	·622	11·9	7·39	·642	12·8	8·24
1890 to 1896 .	·374	22·8	8·52	·467	13·6	6·35	·490	17·4	8·51

The average farm price of wheat declined, as is shown in the above tables, from \$1.05 per bushel for the decade 1870 to 1880 to 65·8 cents for the period 1890 to 1896. The farm prices of the other cereals declined less during the twenty-seven years. Corn declined from an average farm price of 42·6 cents per bushel for 1870-80 to 35·5 cents in 1890 to 1896. The farm value of wheat per acre ranged from \$13 in 1870-80 to \$8.54 in 1890-1896; it then advanced to \$10.86 in 1897, and fell to \$8.92 in 1898. In farm value per acre corn averaged \$11.54 in the decade 1870 to 1880, and \$8.55 in 1890-96. The other cereals declined in the same manner in value per acre. The average production per acre shows nothing conclusive with regard to the fertility of the soil of the country. The expansion of the crop area usually causes a lowering of the average yield per acre by distributing the culture, fertilizers, &c., over more surface. Likewise the contraction of crop area will usually increase the average yield per acre of the entire country. The average bushels of wheat per acre was 12·4 in the decade 1870 to

1880, and 13 in the period 1890 to 1896; of corn, 27·1 in 1870 to 1880, and 24·1 in 1880 to 1896 continuously. Oats fell off from 28·4 to 25·2 bushels per acre from the first to the last period.

The agricultural returns for 1890 to 1899 may be taken as an illustration of the cereal production of the United States. The figures for wheat, oats, and Indian corn are presented in Tables Nos. VII., VIII., and IX.

The acreage and production of wheat have steadily increased; the total farm value of the crop has averaged \$330,000,000 a year for the last ten years. The acreage in Indian corn, the great American crop, reached its highest in 1899, 82,000,000 acres, and its production its highest figure in 1896, 2,284,000,000 bushels.

Producing as the United States does so much more than its people can consume, its exports form a large percentage of some of the crops, as Table X., from the *Year Book* of the Department of Agriculture for 1897, shows.

The average percentage of wheat crop exported annually

TABLE X.—Percentage of Crops Exported. Averages for Period 1878 to 1896.

Crop.	Annual Average.		
	1878-82.	1883-92.	1894-96.
Wheat	27.84	17.68	15.96
Corn	4.82	3.49	5.39
Rye	10.30	...	12.21
Oats37	.80	2.22
Barley	1.55	...	12.96
Potatoes3730
Tobacco	55.84	...	67.42
Cotton	72.80	66.79	73.60

from 1894 to 1896 was 16; of corn, 5.4; of rye, 12.2; of

barley, 13; of tobacco, 67.4; of cotton, 73.6. Large portions of some of these crops, like corn and oats, are exported in the form of animals and animal products (meats, lard, hides, &c.). The hay crop is almost entirely used in this way, and the tendency is to convert more and more of these crops into these higher-priced products. Still, the time is far distant when domestic consumption will come anywhere near overtaking domestic production, especially of wheat and the other cereals. The certain extension of acreage with the growth of demand and price, the increased use of agricultural implements, and the improvement of methods will be sure to keep up a large surplus for export for long years to come. The Department of Agriculture has found that for home use there is required per caput 5.5 bushels of wheat, 28.6 bushels of

corn, and 10·7 bushels of oats, the computations being made from the figures for population, production, and exports for 1888 to 1892. The following number of acres in these crops are required, therefore, to supply the home demand:—0·43 of 1 acre in wheat, 1·15 acre in corn, and 0·43 acre in oats per head of the population. If we take the year 1890 as an illustration, this gave a surplus area in wheat of 11,264,478 acres, of 2,648,404 acres in corn, and of 238,162 acres in oats.

There were 4,008,907 farms in the United States in 1880, and in 1890 there were 4,564,641, an increase of 13·9 per cent. In 1880 the average number of horses to the farm was 2·8, and in 1890, 3·1. In 1880 there was an average of 0·4 mule per farm in the United States, and in 1890 the number had increased to 0·5. There were on the average three milch cows on each farm in 1880, and in 1890 the number had increased to 3·5. The number of other cattle per farm was 5·3 in 1880, and in 1890 it was 8·1. The average number of sheep fell from 10·2 in 1880 to 9·7 in 1890. There was a corresponding decrease in value. The number of swine rose from 8·5 in 1880 to 11·3 in 1890. There were on the average farm in the United States in 1880, 30·2 animals, whose total value was \$393, and in 1890 there were 36·2 animals valued at \$529, an increase in numbers of 19·9 per cent., more than keeping pace with the increase in number of farms, which was 13·9 per cent.; and in value the increase was \$136, or 34·6 per cent.¹

Table XI. shows the average number and value of animals on farms in the United States in 1880 and 1890, with the percentage of increase or decrease during the decade.

In 1880 there were 23 horses to each 100 of population in the United States. The number increased to 25 in 1893, and declined to 21 in 1896. For the decade 1880-90 the average was 21½, and for the period 1890-98 the average was 23. The average value of horses per 100 of population for the ten-years period 1880-90 was \$1462, and for the period 1890-98 \$1300. In 1880 there were 3 mules for each 100 of population, and after increasing to 4 in 1894 it fell to 3 in 1899. The value

of mules per 100 of population increased from \$214 in 1880 to \$296 in 1889, and declined steadily to \$150 in 1898. Since the war with Spain there has been a marked increase in value, which still continues. Between 1880 and 1890 there were about 25 milch cows for every 100 of population. After 1890 the number increased to 26, and in 1896 fell off to 23. The average value of cows per 100 of population increased steadily from \$565 in 1890 to \$780 in 1884, but decreased to \$520 in 1898. The latest reports indicate a marked increase again. The

Total . . .	30·2	393	36·2	529	+19·9	+34·6

number of sheep in proportion to population increased from 82 per 100 in 1880 to 93 in 1884, from which there was a steady decrease to 53 in 1898. The values increased from \$182 per 100 of population in 1880 to \$234 in 1883, from which there was a downward movement, reaching the lowest point, \$92, in 1896. The number of swine per 100 of population commenced with 69 in 1880 and reached their highest point, 85, in 1882, then decreased to 75 in 1888, and to 63 in 1898. The values started at \$295 in 1880, went up to \$550 per 100 in 1883, and then declined to \$270 in 1898. The total value of all farm animals per 100 of population increased from \$3185 in 1880 to the highest point, \$4454, in 1884, from which there was a steady decrease to \$2300 in 1898. The following tables (XII. and XIII.) give the number, total value, and average price of farm animals in 1880, 1890, and 1900:—

1900 . . .	44.61	53.56	31.60	24.97	2.93	...

Since the Civil War the number of horses has increased and prices have gradually declined. In 1893 the number

¹ Condensed from Report of the Division of Statistics of the U.S. Dept. of Agriculture, 1899.

of horses reached the highest figure, 16,206,802, an increase of over 5,005,002, or 44·6 per cent. over the number in 1880. The average farm price of horses increased from \$54·75 in 1880 to \$74·64 in 1884, after which there was an uninterrupted decrease to \$31·51 in 1896. The extension of street-car lines, and the substitution of cable and electric power for that of horses, and the use of bicycles have been factors in decreasing the demand for these animals. The record for mules has been parallel to that for horses.

The returns for milch cows show an increase throughout the period 1880-99 in every year, with the exception of

1895 to 1899. For the first ten years the numbers increased 32.6 per cent., and from 1890 to 1899, .2 per cent. The total value of milch cows increased each year until 1884, then decreased until 1891, with a gradual increase until the end of the period. The farm price of milch cows rose from \$23.27 in 1880 to \$31.37 in 1884, then fell to \$21.40 in 1892, after which there was a steady increase to \$31.60 in 1899.

No marked changes in the numbers of sheep have taken place. During the period 1880-90 there was an increase in numbers amounting to about 8.8 per cent. Since 1893 there has been a rather steady decrease, with fluctuations amounting to a marked depression after 1894. This industry is very susceptible to adverse influences, and felt keenly the depression in the price of wool. The increase commenced again in 1898, and numbers have gone up for two years.

The numbers and values of swine constantly fluctuate with the movement and value of the corn crops. The returns for 1890 showed a numerical increase of 51.6 per cent. over those of 1880; then followed a steady decrease in numbers down to 1897, since which time there has been a slight increase. The movement in values was similar to that in numbers. From \$4.28 in 1880, the average farm price of hogs increased steadily to \$6.75 in 1883. The lowest figure, \$4.15, was reached in 1891, and after numerous fluctuations it became \$4.40 in 1899.

The total value of farm animals had a steady increase from 1880 to 1890, with slight variations in 1885 and

1886. Following 1890 there has been a steady decrease down to the present time, with the exception of slight increases in 1892 and 1893. In 1880 the total value of farm animals in the United States was \$1,576,917,556. In 1890 it had increased to \$2,418,766,028, or 53.4 per cent. In 1896 the value had decreased to \$1,727,926,084, or 28.6 per cent., from the 1890 values, and an increase of 9.6 per cent. over those of 1880.

The exports of live stock and its products have increased enormously in recent years, both in quantity and value. This is especially true of the exportation of beef, cattle, and meat products. The exports of cattle increased from 182,750 in 1880 to 331,720 in 1895, or 81½ per cent., and values from \$13,340,000 in 1880 to \$30,600,000 in 1895, an increase of 129 per cent. The average value of cattle exported has increased from \$19 in 1870 to \$73 in 1880 and \$92 in 1895. It must be said, however, that only the best and heaviest cattle are exported, which command a much higher price than the average of the country.

The total value of farm animals exported from the United States has fluctuated greatly. On the whole, however, the value has increased from \$16,000,000 in round numbers, in 1880, to nearly \$36,000,000 in 1895, or 125 per cent. The following table (No. XIV.), compiled from statistics of the United States Treasury Department, shows, by years, the number and value of each kind of live animal exported between 1880 and 1895, inclusive.

The exports of meat products of all kinds, including

TABLE XIV.—Number and Value of Farm Animals exported from the United States, by years, 1880 to 1895.

canned meats and oleomargarine, are subject to considerable fluctuation, both in quantity and value, rendering it impossible to describe them in a few words. The exports of beef products, which amounted to 241,000,000 pounds, in round numbers, in 1880, increased, with fluctuations, to a maximum of 507,000,000 pounds in 1891, since which time they have decreased to 345,000,000 pounds in 1895. The values of beef products exported from the country fell from \$26,000,000 in 1880 to a minimum of \$15,000,000 in 1887, and reached a maximum value of \$35,000,000 in 1891. The value of beef products exported in 1895 was \$27,000,000, in round numbers. The exports of hog products have varied in a similar manner from 1,230,000,000 pounds in 1880 down to a minimum of 715,000,000 pounds in 1884, reaching 1,160,000,000 pounds in 1890. The exports for 1895 were 1,090,000,000 pounds. Values have varied in a similar manner from a maximum of \$105,000,000 in 1881 down to \$57,000,000 in 1886, and back up to \$93,000,000 in 1894. The exports of mutton show a marked decrease, both in quantity and values. Starting

from a maximum of 3,380,000 pounds in 1881, they have decreased, with many fluctuations, to 101,000 pounds in 1892, but increased suddenly to 2,200,000 pounds in 1894, since which time they have fallen off again. The values of these exports fell from \$258,000 in 1881 to \$9000 in 1892, and increased to \$174,000 in 1894. The exports of oleomargarine were first regularly reported in 1884, and have increased, on the whole, from 40,000,000 pounds in 1884 to 127,000,000 pounds in 1894, and in values from \$4,800,000 in 1884 to \$12,400,000 in 1894. The total value of exported meat products, including canned goods and oleomargarine, has increased from \$111,000,000 in 1880 to \$134,000,000 in 1894 and \$125,400,000 in 1895. The increase for the entire period was about \$14,480,000, or 13 per cent.

The facts with regard to the production, imports, exports, and consumption of wool in the United States are presented in Table XV., compiled from estimates from the Department of Agriculture and the reports of the bureau of statistics of the Treasury Department. The production of wool shows an increase, with fluctuations,

from 232,500,000 pounds in 1880 to 309,748,000 pounds in 1895, an increase of 33 per cent. The imports show numerous fluctuations, both in quantities and values. The total value of the imports of wool in 1895 was \$25,556,421. The exports of domestic wool show an enormous increase, with numerous violent fluctuations, especially in recent years. Starting with 191,551 pounds in 1880, valued at \$71,987, these exports increased in

1895 to 4,279,109 pounds, valued at \$484,463, an increase of 2000 per cent. for quantity and 570 per cent. for value. The exports of foreign wool also show numerous fluctuations. Their lowest value was in 1884—\$343,456, and their highest in 1881—\$991,407. The consumption of wool in the United States has increased from 356,791,676 pounds in 1880 to 509,159,716 pounds in 1895, an increase of nearly 43 per cent.

AMERICAN WHEAT-FARMING.

That wonderful agricultural region, extending from the international line on the north to the 37th parallel, and from the Atlantic Ocean to the 100th meridian, and comprising 26 States, produces 76 per cent. of the American wheat crop. This region, which contains only 30 per cent. of the land surface of the country, but embraces 60 per cent. of its total farm area and 70 per cent. of its improved farm acreage, is the greatest cereal-producing region of the world. Besides wheat, it produces 82 per cent. of the total corn crop, 91 per cent. of the total oat crop, and 83 per cent. of the total hay crop of the United States. The methods pursued in the eastern portion of this region are similar to those used in other parts of the world; but in the north-western portion wheat-growing is carried on on a gigantic scale, and by methods almost unknown anywhere else. The best illustrations of the great or "bonanza" wheat farms, as they are called, are found along the Red River of the North, where it flows between the States of North Dakota and Minnesota.

The wheat grown in the United States is of two distinct kinds. One is the large-kernel winter wheat of the eastern States; the other is the hard spring wheat. The "blue stem" or the "Scotch-Fife" are native varieties of the latter kind grown in Minnesota and the two Dakotas. For flour-making this wheat is considered the best in the world. During the season of 1899 the product of hard spring wheat amounted to nearly 250,000,000 bushels, or two-fifths of the entire wheat product of the United States. Of this, Minnesota and the two Dakotas alone produced 200,000,000 bushels. Minnesota is the greatest wheat-producing State in the Union. Her fields in 1899 covered 5,000,000 acres, and she produced nearly 80,000,000 bushels, which is twice the entire production of all Australia, and more than that of Great Britain and Ireland put together. In Minnesota and the Dakotas the farms are devoted almost exclusively to wheat-growing. Many of them contain from 3000 to 10,000 acres. All operations on farms of this size must be carried on upon a gigantic scale. The country is a very level one, making it possible to use all kinds of machinery with great success. As

there are no mountains or swamps, there is here very little waste land, and every square foot of the vast wheat fields can be made productive.

The first characteristic of a "bonanza" wheat farm is the machinery. The smallest agricultural implement used upon them is a plough, and the largest is the elevator. A hoe or a spade is almost unknown. *Bonanza farms.* Between these two there are machines of all sizes adapted to the needs of the particular work. Let us assume the conditions prevailing upon a bonanza farm of 5000 acres, and briefly describe the process of wheat production from the ploughing of the land to the delivery of the grain in the final market. These great wheat farms were established upon new lands sold directly to capitalists by the railroads. The lands became the property of the railroads largely through Government grants, and they attracted capitalists, who bought them in large bodies and at low prices. The improvements made upon them consist of the cheap wooden dwellings for the managers, dormitories and dining-halls for the men, stables for the horses, and sheds and workshops for repairing machinery. Very little of the land is under fence. Since the desirable lands of the country have been occupied, the prices of these lands have advanced slowly, with the result that the big farms are being divided up into small holdings. After a generation or two, if land continues to rise in the market as it has recently, the bonanza farms will become a thing of the past. At present the best of these lands in the valley of the Red River of the North are worth from \$25 to \$30 an acre. The improvements upon them add about \$5 an acre more. A farm is not considered a big one unless it contains from 2000 to 10,000 acres at least. There are, of course, many small farmers, owning from two to five sections (640 acres in each section), but their methods are more like those of the small farmers in the eastern United States or on the continent of Europe. It is necessary to own a large body of land in order to be able to use the machinery and methods here described. It is hard to convey a just notion of the size of these farms. They stretch away as far as the eye can reach in every direction, making it difficult even for the visitor to conceive their size. The distances across wheat fields are

so great that even horseback communication is too slow. The farms are separated into divisions, and lodging-houses and dining-halls and barns are scattered over them, so as to keep the workmen and teams near the scene of their labour. The men living at one end of the farm may not see those at the other for months at a time. Even then it is necessary to take the meals to the men in the fields rather than allow them to walk or ride to the dining-halls. It is not an unusual thing for a working crew to find themselves at the dinner hour two miles from their hall.

First, after burning the old straw of the previous year—which is real labour in itself, so enormous is its bulk—comes the ploughing. This begins in October.

Ploughing. The plough used has a 16-inch share, turns two furrows, and is drawn by five horses. Each plough covers about 250 acres in a season, travelling an average of 20 miles a day. The ploughing begins in October, and continues a month or six weeks, according to the season. The ploughs are driven in "gangs" under the eye of a superintendent, who rides with them. From eight to ten of these ploughs follow each other around the vast section. If one stands a few rods ahead of them they seem to be following one another in a line; but, if one stands to the right of the "gang," one sees that the line is broken, and that the second plough is a width farther in the field than the leader, and so on for the entire number. Experience shows that it costs about 70 cents an acre to plough the land in this way. About forty men are employed upon a farm of 5000 acres during the ploughing season. The men are paid by the month, and receive about \$25, including their board. They breakfast at five o'clock, take an hour for their dinner at noon—usually in the field—and have their supper at seven. At the end of the ploughing season these particular men are usually discharged. Only eight or ten are kept on a farm of this size throughout the year. The other men go back to their homes or to the factories in the cities, where they await the harvesting and threshing season. The eight or ten who remain upon the farm are employed in doing odd jobs, such as overhauling machinery, or helping the carpenter and blacksmith, or looking after the horses. The wheat region is a country of heavy snows, and of severe, dry cold; but when March comes the snows begin to melt away, and by April the ploughed land is dry enough for the harrow. The harrowing is done with 25-foot harrows, drawn by four horses, and operated by a single man. One man can harrow 60 to 75 acres a day.

The seeding follows immediately with four-horse press drills that cover 12 feet. The harrows and drills are worked in "gangs" as the ploughs were. Each drill will go from 20 to 25 miles a day. When the weather is good the seeding upon a 5000-acre farm will be done in twenty or twenty-five days. It is usual to seed a bushel and a peck of wheat to the acre. The wheat used for this purpose is carefully selected after the harvest of the previous year, and is thoroughly cleaned of foreign seeds. Through years of cultivation, varieties of wheat have been produced which are particularly well adapted to the soil and climate of this region. It has been found more profitable to use the native "blue stem" or "Scotch-Fife" wheat than the seed from any other country, or even from the neighbouring States. Counting the seed, wheat, and the labour, it costs about \$1 an acre to harrow the ground and plant the wheat.

When the planting is done the extra labourers are discharged again, and the regular ones are put to work on the corn, oats, and millet, which are grown to feed the horses. The men who do the most important work are all temporary labourers. They come

from the cities of the east or the farms of the south. They begin with the early harvest in Oklahoma, and work northwards up the Missouri and the Red River until the season closes in Manitoba. They are not tramps, but steady, industrious men, with few bad habits and few ambitions. On well-managed farms drinking and gambling are strictly forbidden. The work is hard, and, as there are few amusements of the farm, the men spend their resting periods in sleep. Their dormitories are usually comfortably furnished, their dining-halls clean. The bonanza farmers find it good policy to feed their men well. Many a strike has occurred in the midst of the harvest because the quality or quantity of the food served was not what it ought to have been. The largest part of this food is brought from the eastern States. Some potatoes, turnips, and beans are grown upon the farms; but the corned beef, bacon, and groceries come from the cities. It is estimated that it costs 35 cents a day to feed each labourer. Farmers say that a good name in these respects enables them to get the choice of workmen, and that no money brings such sure returns as that expended in the bedrooms and upon the food.

The harvest labourers begin to arrive from the south about the middle of July, and by the end of this month the harvest is at its height. A farm of 5000 acres will use 75 or 100 extra men. With the men comes the new machinery in train loads.

It is estimated that at least \$5,000,000 worth of agricultural machines is annually sold in this region. The wheat farmers say that it does not pay to take undue care of old machinery, that more money is lost in repairing and tinkering an old machine than would pay for a new one. The result is that new machinery is bought in very large quantities, used until it is worn out or cannot be repaired without considerable work, and then left in the fields to rust. Heaps of cast-iron can be seen already upon many of the large farms. Of course a great many extra parts are bought to take the place of those which break most frequently, and some men are always kept at work repairing machines in the field. One of the big 10,000-acre farms will use up two car-loads of twine in a single harvest, enough to lay a line around the whole coast of England, Ireland, and Scotland. The harvesters vary in size according to the character of the land. Upon the rougher ground and small farms the ordinary binders are used; upon the great plains, like those of California, a great harvester is used, which has a cutting line 52 feet wide. These machines cut, thresh, and stack the grain at the rate of 1600 sacks a day, and cover an area in that time of 100 acres. These machines can only be used where the wheat ripens thoroughly standing in the field. The harvest labourer earns \$10 a week everywhere in America. The bonanza farmer expects one machine to cut at least 250 acres, and three men are required for each of them. The harvest lasts from ten days to three weeks, according to the weather. Including the labour and the wear and tear, it costs about 60 cents an acre to harvest wheat.

The wheat is not stacked as in the eastern States and in England, but stands upright in shocks in the field. The grain cures very rapidly in the dry climate, so that by the time the wheat is all cut and shocked on one end of the division, it is ready for the thresher at the other. The shocks of wheat are hauled directly to the thresher and fed into the self-feeder. It usually takes a day and a quarter to thresh the wheat which it took a day to cut. The farmer estimates that a threshing-machine can thresh all the wheat ordinarily grown upon 2500 acres, so that a 5000-acre farmer would have at least two machines running at the same time. Time is a very important thing in threshing, since a rain-fall might spoil enough grain in one night to buy several

machines. The threshing season is thus a time of great pressure and of extensively active work. The wheat straw is worse than a waste product—it is a great nuisance upon the bonanza farm. A little of it is used for fuel for the engines and for bedding the stock; but the bulk of it is dragged away from the threshing machine by machinery, and left lying in great heaps until an opportunity is afforded for burning it up. This is usually done immediately before the ploughing in the autumn. The grain falls from the spout of the thresher into the box wagon, which carries it to the elevator. The elevator is placed at the railway station, and is usually owned by the bonanza farmer.

From the time the sheaves of wheat are tumbled into the wagon until the flour reaches the hands of the cook, no hand touches the wheat that passes through the great Minneapolis mills. When the box-wagons reach the elevator the loosing of a bolt dumps the grain into the bin, where it remains until the pulling of a lever lets it into the cars. Every pound of it is weighed and accounted for, and entered upon the books, so as to show the exact product of each division of the farm. After the rush of the threshing is over the farmer studies these books carefully to see what his land is doing, and makes his plans for the next year, so as to rest or strengthen those divisions which are failing. It costs about \$1.50 an acre to thresh the grain and put it into the elevator. This sum, added to the estimated cost of the other processes mentioned above, makes the total cost of growing an acre of grain about \$3.80. This includes the cost of labour, seed, and wear and tear of machinery, but does not include the interest on land or plant. The taxes on land will average 25 cents an acre. The farmers estimate that the other improvements, the water-works, elevators, insurance, horse feed, &c., will make this up to \$6 an acre. The best of these farms will yield 20 bushels to the acre. This makes the wheat cost 30 cents a bushel. During the last five years the average farm-selling price of wheat in the North-West has been 58 cents. An acre thus produces \$11.60, making a gross profit of \$5.60. Still to be provided for is the interest on the operating expenses for eighteen months, which will, at 8 per cent., be 48 cents per acre. Interest on the capital in land, improvements, and machinery, at \$30 per acre, makes \$1.80 more, or a total interest charge of \$2.28. When this is deducted from the gross profits of \$5.60 prices found above, we have a net profit of \$3.32 an acre, not an exorbitant one by any means. This is about 8 per cent. on the capital invested in the land, plant, and operating expenses. But we have described the conditions on one of the best bonanza farms. The average yield per acre in this region is not over 18 bushels, and the average expenses would be higher than those given.

Every bonanza farmer's office is connected by wire with the markets at Minneapolis, Chicago, and Buffalo. Quotations arrive hourly in the selling season, and the superintendent keeps in close touch with his agents in the wheat-pits of these and other cities. When the instrument tells him of a good price, his agent is instructed to sell immediately. The farmer on the upper waters of the Red River of the North is kept fully informed as to the drought in India, the hot winds in the Argentine, and the floods of the Danube. Any occurrences in these distant parts of the world are known to him in a surprisingly short time. The world's great wheat fields almost lie within his sight, so well does he know the conditions that prevail in them. Ten days are allowed for delivery, so that he can usually ship the wheat after it is sold. In the early days of wheat-farming the bonanza farmer often speculated, but experience has taught him that he had

better leave this to the men in the cities, and content himself with the profit from the business under his eye. The great elevator centres are in Duluth, and Minneapolis, Chicago, and Buffalo. These elevators have a storage capacity of from 100,000 to 2,500,000 bushels. The new ones are built of steel, operated by steam or electricity, protected from fire by pneumatic water-pipes, and have complete machinery for drying and scouring the wheat whenever it is necessary. The elevators are provided with long spouts containing movable buckets, which can be lowered into the hold of a grain-laden vessel. The wheat is shovelled into the pathway of the huge steam shovels, which draw it up to the ends of these spouts, where the buckets seize it, and carry it upwards into the elevator, and distribute it among the various bins according to grade. A cargo of 200,000 bushels can thus be unloaded in two hours, while spouts on the other side of the elevator reload it into cars, five to ten at a time, filling a car in from five to ten minutes, or the largest canal boat in an hour. The entire work of unloading, storing, and reloading adds only one cent to the price of a bushel of wheat.

The great wheat-growing States like Minnesota have established systems of inspecting and grading wheat under State supervision. In Minnesota the system is carried out by the Railway and Warehouse Commission, which fixes and defines the different grades of wheat and directs the work. At present there are 18 grades recognized in this State. The first is described as "No. 1, hard spring wheat, sound, bright, and well cleaned, composed mainly of hard 'Scotch-Fife,' weighing not less than 58 lb to the measured bushel." The second grade is known as "No. 1, northern spring wheat, sound, and well cleaned, composed of the hard and soft varieties of spring wheat." So the varieties run—"No. 2, northern"; "No. 3, northern," &c.—down to the 18th, which is "no grade." The official inspectors examine, grade, and sample the wheat in the cars in which it is received at the great markets or elevators. The cars are sealed at the point of original shipment. The first thing, therefore, is to examine the seals to see that they are unbroken. The inspector then samples and examines the wheat, and enters the grade upon a blank opposite the number and letters of the car. His tag and sample go to the wheat exchange or chamber of commerce, where they are exposed in small tin pans, and form the basis of the trading. A few years ago the wheat received from the North-West was very clean indeed, but since the new land has all been cultivated the fields are growing more weedy, with the result that the wheat brought in is becoming mixed with oats and seeds of weeds, requiring more careful separating and inspection. After the inspector has finished his work the cars are resealed with the State seal, and await the orders of the purchaser. The delay will not ordinarily be more than one day. The Commission keeps complete records and samples of each car until the wheat has passed entirely out of the market. When disputes occur as to the grade they can thus be instantly settled. If the grade is changed after a second examination the State pays the expense of the inspection; if not, it is paid by the agent who raises the objection. Only about 5 per cent. of the samples are ever reinspected, and in less than 2 per cent. of these is the grade changed. The Commission collects the small fee of 20 cents a car for its services as inspector, and later weighs all the wheat as it is distributed into the elevators. This small charge pays all the expenses.

The transportation of the wheat from the fields of the North-West to the seaport is a business of tremendous magnitude. Most of this wheat goes by way of the lakes through the Sault de Sainte Marie canal to Buffalo, where

it is shipped by rail or inland canal to New York, Philadelphia, or Baltimore. Duluth, on Lake Superior, is, surprising to say, the second port in the United States in point of tonnage. The Sault de Sainte Marie canal passes two and a half times as much tonnage during the eight months it is open as the Suez canal passes in the entire year. The cheapest transportation in the world is found upon these lakes, the rate being only three-fourths of a mill per ton of wheat per mile. The greater lake vessels, called "Whalebacks," carry cargoes up to 250,000 bushels, a bulk difficult to conceive. 700 bushels is a car-load. At that rate the cargo of 250,000 bushels will fill 360 American cars, or 9 trains of 40 cars each. At 20 bushels to the acre, this single cargo would represent the yield of two and a half farms of 5000 acres each, like that described above, with every acre in cultivation. The railways of the North-West have a monopoly of the business of hauling wheat, with the result that it costs 20 cents to ship a bushel of wheat from the Dakota fields to Duluth, which is as much as it costs to forward it from Duluth to Liverpool. The bushel of wheat, or an equivalent amount of flour, can be shipped from Minneapolis or Duluth to almost any point in western Europe for from 20 to 25 cents.

What are the prospects of wheat production in the United States? In his presidential address before the

British Association for the Advancement of Science (1900), Sir William Crookes painted a rather dark picture of the future of the world's wheat production. Among other things he said;

"It is almost certain that within a generation the ever-increasing population of the United States will consume all the wheat grown within its borders, and will be driven to import like ourselves." Americans think that this statement is altogether too pessimistic. Not sufficient account had been taken of the uncultivated land in farms, and of the possibilities of improving the yield, and still further cheapening the product. It is probable that the United States will by 1933 have a population of 133,000,000. This population would require a wheat crop of 700,000,000 bushels for its own use alone. Limiting attention to the great cereal-producing region described above, let us see what the prospects are for increasing the acreage and the yield. The fact that these States contain, according to the last census, over 100,000,000 acres of unimproved land, already enclosed in farms, suggests at once the great possibilities in wheat. But all this land is not immediately available for cultivation. The availability of the unimproved land in these States is chiefly a question of population and physical features. In States like New York and Pennsylvania, which are much broken up by hills and mountains, and have already a large population, it is probable that the land available for wheat cultivation is now nearly all taken up, although they still have 30 per cent. of unimproved land in farms. In the great States of Michigan, Missouri, Wisconsin, Minnesota, and the Dakotas there is still 40 to 50 per cent. of unimproved land in farms. There are few mountains and hills in these States, and there is still room in them for a large population. It is evident that in States like these wheat culture is destined to increase greatly. Twelve States in this vast cereal-growing region—Ohio, Indiana, Illinois, Missouri, Kansas, Nebraska, Michigan, Iowa, Wisconsin, Minnesota, North and South Dakota—still have from 20 to 40 per cent. of unimproved land in farms. The total area of these States is nearly four times that of France. Their soil is primarily as fertile as hers. If we put the population of France at 40,000,000, the States in question could, at the same ratio, support a population of 140,000,000. France produced during the five years ending 1897 eight bushels of

wheat per caput. At eight bushels per caput, the people in these twelve States alone could produce 1,120,000,000 bushels, or 420,000,000 bushels more than will be required by the population of 133,000,000 expected by 1933. This is a great manufacturing as well as a great agricultural region, and it is here, therefore, that a large part of this increase in population will be found.

It is evident that there is great room for improvement also in the matter of yield per acre. The average yield of wheat per acre has increased slowly in recent years. So long as there was so much virgin land to be brought under cultivation, it is surprising that it has increased at all, since the tendency everywhere is to "skin" the rich, new lands first. Mr B. W. Snow, formerly one of the statisticians of the United States Department of Agriculture, has shown (*The Forum*, vol. xxviii. p. 94) that the producing capacity of the wheat lands, under favourable weather, increased steadily during the period 1880-1899. He distinguishes between the actual yield and the producing capacity, and bases his comparison upon the latter. He takes the average for each year of five years between 1880-1899, and shows that the producing capacity per acre increased 0.5 bushel between the first and the second period, 1.3 bushels between the second and the third, and 1.4 bushels between the third and the fourth. In the period 1880-84, inclusive, the maximum capacity was a little less than 14 bushels, while in the period 1895-99 the maximum capacity exceeded slightly 17 bushels—an increase of 3.2 bushels per acre, or 23 per cent., in less than twenty years. He says, "To account for this increase in the potential yield in our wheat-fields many factors must be taken into consideration. Among these may be mentioned improved methods of ploughing, tile drainage, use of the press drill, which results in greater immunity against winter killing, crop rotation, and, to a very small extent, fertilization. An important factor to be mentioned in this connexion is the change in the distribution of the acreage under wheat, consequent upon falling prices. A decline in the price of wheat rendered its production unprofitable where the rate of yield was small. Gradually these lands were passed over to crops better suited to them; while at the same time the wheat acreage was increased in districts having a better rate of yield." He predicts that "the increase in the acre yields in this country has only begun. All that has been accomplished during the period under review may be attributed to improvements in implements for preparing the soil and planting the seed. Wheat is grown year after year without rotation—except in a few cases—on a third or more of our wheat acreage; not one acre in fifty is directly fertilized for the crop, and only a minimum amount of attention is given to the betterment of seed stock. If, in the face of what cannot be considered less than careless and inefficient agricultural practice, we have increased the wheat capacity of our land by 3.2 bushels per acre in so short a time, what may we not expect in the way of large acre yields before we experience the hardships of a true wheat famine?"

COTTON.

Soil and climatic conditions restrict the cultivation of cotton to a group of States in the southern portion of America constituting less than one-fourth of the total area of the United States, yet these States grow over 60 per cent. of all the cotton consumed in the world. The total value of the annual crop is exceeded among the cultivated crops of the United States only by Indian corn, which is grown in every State, and about one year in four by wheat, which is grown in almost every State. Its production engages almost exclusively 7,000,000 of

the people, and its handling for domestic and foreign markets employs the capital or labour of several millions more.

Cotton is limited by climatic conditions to the States south of latitude 37° N. The essential features of the climate in this section are the long warm season and the peculiar distribution of the rainfall. Cotton is a sun plant. Fluctuations in yield per acre in a given place are less in the case of cotton than in any other product of the soil; in other words, a certain amount of sunlight produces a certain amount of cotton. This may be due to the greater uniformity of all the climatic conditions obtaining in the cotton belt; but the determining condition as between different sections is the amount of light and heat distributed over the required number of months. This period is ordinarily measured by the date of the last killing frost in the spring and of the earliest frost in the fall. Cotton-picking may be extended far into the winter, but the first killing frost stops the active growth of the plant, and by killing the blossoms and young bolls puts an end to the production of cotton for that season. Cotton requires for its development from six to seven months of favourable growing weather. It thrives in a warm atmosphere, even in a very hot one, provided it is moist and the transpiration does not overtax the leaves. The plant requires, however, an abundant supply of moisture during the growing stage. A rainfall increasing from the spring to the middle of summer and then decreasing to autumn is probably the most favourable condition for the production of this crop. These are exactly the conditions that prevail in the cotton States. Cotton grows more or less successfully on nearly all kinds of soil within this climatic belt. Light sandy soils, loams, heavy clays, and sandy "bottom lands" will all grow it, though not with equal success. Sandy uplands produce a short stalk, which bears fairly well. Clay and bottom lands grow a plant of large size, yielding less lint in proportion. The best soils for cotton are the medium grades of loam. The cotton soil should be of a quality to maintain very uniform conditions of moisture. Sudden variations in the amount of water supplied injure the plant decidedly. A sandy soil does not retain water; a clay soil maintains too much moisture and causes the plant to take on too rank a growth. The best soil for cotton, therefore, is a deep, well-drained loam. Cotton is successfully grown in the south on nearly all kinds of soils, from the piny ridge soils of North Carolina to the rich bottom soils on the Mississippi.

The cotton-growing States include those on the Atlantic slope from North Carolina to Florida and on the gulf from Florida to New Mexico; also the south-western portion of Tennessee, the State of Arkansas, and a portion of Oklahoma. A little cotton has also been grown in Utah and California. The cotton-growing region measures over 550,000 square miles, which is about one-fourth of the total, or one-third of the settled, area of the United States. In 1890 over 50 per cent. of this was in farms, and over 20 per cent. was improved, but only about 5 per cent. of the total area, or one-tenth of the area in farms, and one-fourth of the area of improved land, is annually cultivated in cotton. Since the present methods of cultivation require about two and one-half acres to produce one 400-pound bale, the area now in farms in this section would, if all cultivated in cotton, produce over 80,000,000 bales. So far, therefore, as climatic conditions are concerned, the Southern States could produce eight times as much cotton as they have ever done without taking in any more land.

The question of labour required for the production of a cotton crop is a serious one. Expert estimates place the

amount of human labour at about 54 per cent. of the whole expense of growing the crop. This is a much higher ratio of the cost of labour than is found in most other industries. It exceeds the cost of labour in corn, and wheat-growing, and also in manufacturing industries. In the cotton mills reporting to the Department of Labour the average cost of labour employed is only about 28 per cent. In 1880 the people in the cotton belt produced an average of 231 pounds of cotton per caput; in 1890 this had been increased to 254; and in the State of Mississippi, where conditions are most favourable, the production per caput was 427 pounds in 1889. With their present population, and under present conditions, the Southern States yield 300 pounds per caput. The total population of the cotton States may be fairly placed at 15,000,000. This population could easily produce a far larger crop than it does now, for there is great room for improvement in methods of cultivation and fertilization. There are three classes of farmers engaged in cotton cultivation, namely, owners of the land, renters who pay money rental, and share croppers. In the ten principal cotton States, according to the census of 1890, there were 57 per cent. of the first class, 15 per cent. of the second, and 28 per cent. of the third.

The result of a careful inquiry as to the cost of producing cotton in the United States, made in 1897 by the Department of Agriculture, gives an average cost per acre on upland farms of \$15.42, and the average total return of cotton fibre and seed \$19.03, the average net profit being \$3.61. The average yield is 255.6 pounds of lint and 16 pounds of seed per acre, and the average price of lint 6.7 cents per pound and of seed 11.9 cents per bushel. The average cost of picking one hundred pounds of cotton is 44 cents and the average cost of producing lint cotton in all the States and territories is 5.27 cents per pound. Eighty per cent. of the cotton plantations reporting in 1896 showed a profit and 20 per cent. a loss.

Figure 1 shows in a graphic manner the record of cotton production in the United States every tenth year from 1790 to 1890, and also for the year 1895; the portion of each crop consumed at home (divided between north and south), and the portion exported.

A cotton crop of 9,000,000 bales, such as that of 1899, represents at 7 cents a pound a money value of \$300,000,000. Of this amount, 70 per cent. is exported, bringing into the country about \$210,000,000. Basing the calculation on the average price of each year, the cotton crops in America for the last one hundred years have been worth \$15,000,000,000. During the hundred years about 82,000,000,000 pounds have been exported, representing a value of \$11,000,000,000. In 1790 Great Britain received from America something less than one six-hundredth part of her total cotton imports, but only fifty years later she received from the Southern States four-fifths of all the cotton she used; and the South has always maintained and still maintains its position in relation to the cotton consumption of the world. It has never supplied less than 80 per cent. of the cotton used by Great Britain and the United States together, and in 1892 the Southern cotton formed 82 per cent. of the total amount consumed in these two countries.

In the next chart (Fig. 2) an attempt is made to present in somewhat greater detail the chief facts with regard to area, production, exports, and values of the cotton crop during the ten years from 1886 to 1896. It shows that an average area of a little less than 20,000,000 acres, cultivated each year, has produced in these ten years a total of over 36,000,000,000 pounds, valued at more than \$3,000,000,000. Of the total production of

Labour.

Production
and
Exports.

these ten years we exported 24,600,000,000 pounds, worth \$2,250,000,000. The amount exported was 68.3 per cent. of the entire production, leaving only 31.7 per cent. for home consumption. The average yield per acre during the last ten years was only 181 pounds and the average New York price was nearly 9 cents per pound, making the average value per acre nearly \$16.

more promptly or more generously to judicious fertilization than does the cotton plant. The results obtained upon about fifteen hundred representative cotton plantations in the five Atlantic coast States—North Carolina, South Carolina, Georgia, Alabama, and Florida, where fertilizers have been longest and most used—were tabulated according to the cost of fertilizer per acre. Six classes were

formed, ranging from under one dollar's worth to six dollars' worth and over of fertilizer. The planters who spent an average of 74 cents for fertilizers per acre made an average profit of \$4.62; those who spent from \$1.00 to \$2.00 for fertilizers made a profit of \$5.09; from \$2.00 to \$3.00, a profit of \$5.34; from \$3.00 to \$4.00, a profit of \$5.91; from \$4.00 to \$5.00, a profit of \$7.96; and those whose fertilizers cost them \$6.00 and more per acre made a profit of \$12.51. The word *profit* was used in this investigation to mean "the excess of returns over expenses, including the theoretical one of rent." "Some small charges, such as insurance, repairs, renewals, and supervision, were omitted." "It is evident from the figures above that the point of diminishing returns was not reached, when the crop was profitable, at any degree of fertilization." The total number of plantations reporting losses is

Fig. 1.

Most interesting and instructive are the results of the investigations made by the Department of Agriculture in 1897 with regard to the use of fertilizers upon cotton. They show that no plant responds

only 15 per cent. "The returns from the planters who suffered a loss, while at first seeming to indicate a conclusion contrary to the above, in reality do not, because their crops were subject to abnormal conditions

COTTON IN THE UNITED STATES.

Fig. 2.

and were partial failures, the cause generally having been a drought." "In cases of the planters who lost on their crops the loss is greater as the cost of fertilizers is greater; but had climatic conditions been favourable, the loss would have been a profit." Co-operative experiments by selected farmers, directed by the experiment stations, show that the application of 60 pounds of nitrogen, 20

pounds of potash, and 20 pounds of phosphoric acid in suitable form, made on fair average land, containing a reasonable amount of humus, such, for example, as would without fertilizer produce 250 pounds of lint per acre, would usually double this crop. Cotton-seed meal, the offal of fisheries, abattoirs, &c., are the commonly used sources of nitrogen; the superphosphates are made from

Carolina, Tennessee, or Florida phosphates; and the potash salts are imported from Germany. These are commonly mixed to produce a fertilizer containing about 2½ per cent. of nitrogen, 9 per cent. of soluble and reverted phosphoric acid, and 2 per cent. of potash. Such a fertilizer can usually be laid down upon the farms in the cotton country for about \$5.00 per acre for the above amounts. Five dollars invested in this kind and amount of fertilizer will, upon land of the character described, with favourable weather, produce an increase in the crop amounting to \$10.00 to \$15.00. Fertilizers are gradually being introduced throughout the cotton country, with the exception of the rich bottoms of the Mississippi and the black prairies of Texas, where they have so far never been needed.

Great improvements have also been made in the implements and in the methods of cultivation. This crop, which under the slave system was cultivated almost entirely with the hoe, is now cultivated wholly with machines. On many plantations the hoe is used only once, to thin the cotton. The culture is carried out with horse cultivators and is prosecuted as long as the growth of the plant continues, or until the actual fruiting begins. According to the reports to the Department of Agriculture the percentage of each item in the total average cost of cultivating a crop of cotton is as follows:—Rent of land, 19; ploughing, 18; seed, 1; planting, 2; fertilizers and distributing, 9; thinning and hoeing, 8; picking, 22; ginning and pressing, bagging and ties, 11; wear and tear on implements, 3; marketing and other expenses, 7 per cent. It will be seen that picking is much the most expensive item in cotton cultivation. The great desideratum still is the cotton-picking machine.

The cotton-plant has undergone a remarkable development since its introduction in the southern States. The

Varieties. cultivated cottons of to-day differ much from the original form of *Gossypium herbaceum*, which produced seed cotton, whose lint was only 25 per cent. of its weight, and had a staple only 20 to 30 mm. long. Under the influence of the climate, soils, and cultivation of these States the proportion of lint has been greatly increased, reaching as high as 36 and even 40 per cent. in some varieties; while the length of the staple has increased correspondingly, reaching in a few varieties a length of 50 or even 60 mm. In only a few varieties, however, have we obtained this great increase in both percentage of lint and length of staple. Usually, when the length and fineness of the staple are increased the weight is reduced, and *vice versa*. In cases where both length of fibre and weight have been increased the cotton runs down again very rapidly, first usually in the weight produced. Cotton is a plant which supports easily and responds quickly to differences in environment, soil, climate, treatment, and manures, and can thus be greatly modified in form and habit in a few successive generations. The flowers are open; the pollen is produced in great abundance, and is borne upon the slightest breeze. The stigmas are well above the anthers, so that cross-fertilization is easy and common. Seeds from the earlier maturing bolls produce plants yielding a longer lint than those from the later-ripened bolls on the same plant. Some varieties produce a long, silky fibre when grown in rich, moist soil, but soon lose these qualities when grown on the poorer hill lands. A variety which has been grown for years in the northern belt of the cotton region will mature its whole crop at the same time, while the same variety grown for a few years in the southern part of the belt will continue to ripen through several weeks, though the total yield will be no greater. With this natural tendency to vary, and with all these forces to impel the plant to change its form

or habit, varieties are multiplied indefinitely, even without the help of the cultivator. Of true botanical varieties, however, there are few, if any; while the agricultural varieties, so called, are almost innumerable. The result of this natural tendency of the plant is that the names of agricultural varieties are in great confusion, and there is a good deal of humbugging connected with the business of selling cotton-seed for planting. The natural tendency of this variation is always back towards its original form. Unusual fruitfulness always results in loss of vitality, and the original form, yielding a small crop, always has the greater vitality, and so a greater prepotency in cross-fertilization. As a result of this law, constant care in the selection of seed is essential in order even to keep an improved variety up to its present standard. Only the seed from the finest typical plants should be saved and used. The neglect of these principles leads surely to degeneration of the so-called improved variety. In this way planters are often disappointed with the results secured from high-priced seed of new varieties, for which great claims are made by their originators, and large prices paid. The old method of saving seed for planting was to take a sufficient number of bushels just as they came from the gin. The new method of selecting the best plants only of the typical form is resulting in the steady improvement of the cotton-plant. If it is intelligently pursued by a large number of planters for another century, or even a score or two of years, it will certainly result in the still further improvement of this wonderful plant. The great desire, of course, is to secure a cotton-plant which will yield a maximum amount of fibre of the longest and finest staple. It is believed by experts that cotton will be improved steadily until this end is reached.

The culture of cotton must be a clean one. It is not necessarily deep culture, and during the growing season the cultivation is preferably very shallow. The result of this is a great destruction of the humus **Culture.** of the soil, and great leaching and washing, especially in the light loams of the hill country. The main object, therefore, of the cotton-planter is to prevent erosion. Wherever the planters have failed to guard their fields by hillside ploughing and terracing, these have been extensively denuded of soil, rendering them barren, and devastating other fields lying at a lower level, which are covered. The hillsides have to be gradually terraced with the plough upon almost an exact level. On the better farms this is done with a spirit-level or compass from time to time, and hillside ditches put in at the proper places. In the moist bottom-lands along the rivers it is the custom to throw the soil up in high beds with the plough, and then to cultivate them deep. This is the more common method of drainage, but it is an expensive one, as it has to be renewed every few years. More intelligent planters drain their bottoms with underground or open drains. In the case of small plantations the difficulties of adjusting a right-of-way for outlet ditches have interfered seriously with this plan. Many planters question the wisdom of deep-breaking and subsoiling. There is no question that a deep soil is better for the cotton-plant; but the expense of obtaining it, the risk of injuring the soil through leaching, and the danger of bringing poor soil to the surface, have led many planters to oppose this plan. Sandy soils are made thereby too dry and leachy, and it is a questionable proceeding to turn the heavy clays up upon the top. Planters are, as a result, divided in opinion as to the wisdom of subsoiling. Nothing definite can be said with regard to a rotation of crops upon the cotton plantation. Planters appreciate generally the value of broad-leaved and narrow-leaved plants and root crops, but there is an absence of exact knowledge, with the result that their

practices are very varied. It is believed that the rotation must differ with every variety of soil, with the result that each planter has his own habit in this respect, and little can be said in general. A more careful study of the physical as well as the chemical properties of a soil must precede intelligent experimentation in rotation. This knowledge is still lacking with regard to most of the cotton soils. The only uniform practice is to let the fields "rest" when they have become exhausted. Nature then restores them very rapidly. The exhaustion of the soil under cotton culture is chiefly due to the loss of humus, and nature soon puts this back in the excellent climate of the cotton-growing country. Fields considered utterly used up and allowed to "rest" for years, when cultivated again, have produced better than those which had been under a more or less thoughtful rotation. In spite of the clean culture, good crops of cotton have been grown on some soils in the south for more than forty successive years. The fibre takes almost nothing from the land, and where the seeds are restored to the soil in some form, even without other fertilizers, the exhaustion of the soil is very slow. If the burning-up of humus and the leaching of the soil could be prevented, there is no reason why a cotton soil should not produce good crops continuously for an indefinite time. Bedding up land previous to planting is almost universal. The bed forms a warm seed-bed in the cool weather of early spring and holds the manure, which is drilled in usually, to better advantage. The plants are generally left 2 or 3 inches above the middle of the row, which in 4-foot rows gives a slope of one inch to the foot, causing the plough to lean from the plants in cultivating, and thus to cut fewer roots. The plants are usually cut out with a hoe from 8 to 14 inches apart. It seems to make little difference exactly what distance they are, so they are not wider apart on average land than 1 foot. On rich bottom-land they should be thinner. The seed is dropped from a planter, five or six seeds in a single line, at

regular intervals 10 to 12 inches apart. A narrow, deep furrow is usually run immediately in advance of the planter, to break up the soil under the seed. The only time the hoe is used is to thin out the cotton in the row; all the rest of the cultivation is by various forms of ploughs and so-called cultivators. The question of deep and shallow culture has been much discussed among planters without any conclusion applicable to all soils being reached. All grass and weeds must be kept down, and the crust must be broken after every rain, but these seem to be the only principles upon which all agree. The most effective tool against the weeds is a broad, sharp "sweep," as it is called, which takes everything it meets, while going shallower than most ploughs. Harrows and cultivators are used where there are few weeds, and the mulching process is the one desired. The date of cotton-planting runs from 1st March to 1st June, according to situation. Planting commences early in March in Southern Texas, and the first blooms will appear there about 15th May. Planting may be done as late as 15th April in the Piedmont region of North Carolina, and continue as late as the end of May. The first blooms will appear in this region about 15th July. Picking may commence on 10th July in Southern Texas, and continue late into the winter or until the rare frost kills the plants. It may not begin until the 10th of September in Piedmont, North Carolina. It is a peculiarity of the cotton-plant to lose a great many of its blooms and bolls. When the weather is not favourable at the fruiting stage the otherwise hardy cotton-plant displays its great weakness in this way. It sheds its forms, as the buds are called, its blooms, and even its half-grown bolls in great numbers. It has frequently been noted that even well-fertilized plants upon good soil will mature only 15 or 20 per cent. of the bolls put on. No means is known so far for preventing this great waste. Even experts are at an entire loss to form a correct idea of the cause or to apply any effective remedy.

TABLE XVI.—Acreage, Production, and Value, Prices, and Exports of Cotton in the United States, 1875-1898.¹

¹ From the Year-Book, U.S. Department of Agriculture, for 1899.

Cotton-picking is at once the most difficult and most expensive operation in cotton production. It is paid for at the rate of from 45 to 50 cents per cwt. of seed cotton. This is light work, and is effectually performed by women

and even children, as well as by men; but it is tedious, and requires care. The picking season will average 100 days. It is difficult to get the hands to work until the cotton is fully opened, and it is hard to induce them to pick over 100 lb a day, though some expert hands are found in every cotton plantation who can pick twice as much. The loss resulting from careless work is very serious. The cotton falls out easily or is dropped. The careless gathering of dead leaves and twigs, and the soiling of the cotton by earth or by the natural colouring matter from the bolls, injure the quality. It has been commonly thought that the production of cotton in the south is limited by the amount that can be picked, but this limit is evidently still very remote.

The negro population of the towns and villages of the cotton country is usually available for a considerable share in cotton-picking. There is in the cotton States a rural population of over 7,000,000, more or less occupied in cotton-growing, and capable, at the low average of 100 lb a day, of picking daily nearly 500,000 bales. It is evident, therefore, that if this number could work through the whole season of 100 days, they could pick three or four times as much cotton as the largest crop ever made.

The comparative figures in Table XVII., compiled from the reports of the bureau of statistics of the Treasury Department, show the number of bales of cotton exported to each foreign country in 1889, as compared with the years 1898 and 1899. All bales are reduced to the uniform weight of 500 pounds each.

TABLE XVII.—Exports of Cotton from United States to Foreign Countries.¹

Total	4,769,633	237,775,270	7,700,529	230,442,215	7,546,821	209,563,874

¹ From the *Year Book*, U.S. Department of Agriculture, for 1899.

Except in the cases of Belgium and Russia, the increase in exports has been very large, in some cases the amount being more than double what it was eight or ten years earlier. Notwithstanding a net decrease of 153,708 bales in 1899 as compared with 1898, these two years are conspicuous as having recorded the largest exports of cotton in the history of the United States (see Table XVI.). The extremely low prices in 1897-98 and 1898-99 reduced the export values \$7,333,055 in the former, and \$28,211,396 in the latter year, as compared with those of 1889, although the number of bales exported in 1898 was 2,930,896, and in 1899 was 2,777,188 greater than in 1889.

While there are no available statistics showing the annual crops of all the cotton-producing countries, the consumption of the mills in Great Britain, the Continent of Europe, the United States, India, Japan, Canada, Mexico, and other countries fairly approximates the world's production. The following statistics (Table XVIII.) taken from Dr Thomas Neilson's *Annual Review of the Cotton Trade*, issued in Liverpool, 1st November 1899, show the number of bales of cotton consumed by the mills of the world from 1890-91 to 1898-99, inclusive:—

TABLE XVIII.—The World's Consumption of Cotton,
1890-91 to 1898-99.

In bales of 500 pounds.

Year ended Sept. 30.	Great Britain.	Continent of Europe.	United States.	India.	All other Countries.	Total.
1891	3,394,000	3,631,000	2,867,000	924,000	150,000	10,456,000
1892	3,331,000	3,640,000	2,576,000	914,000	160,000	10,471,000
1893	2,866,000	3,692,000	2,551,000	913,000	220,000	10,247,000
1894	3,238,000	3,848,000	2,264,000	959,000	250,000	10,554,000
1895	3,250,000	4,030,000	2,743,000	1,074,000	300,000	11,397,000
1896	3,276,000	4,160,000	2,572,000	1,105,000	419,000	11,532,000
1897	3,224,000	4,388,000	2,788,000	1,004,000	488,000	11,322,000
1898	3,492,000	4,628,000	2,982,000	1,141,000	713,000	12,576,000
1899	3,519,000	4,896,000	3,558,000	1,297,000	727,000	13,992,000

These figures certainly show a very large increase in the consumption of cotton, the increase in all countries in 1898-99 over the previous year amounting to 1,056,000 bales, of which more than one-half was in the United States, while the increase in all countries since 1890-91 amounts to 3,476,000 bales. In 1898-99 this increase, as compared with the previous year, amounts to 591,000 bales, as against 208,000 in all continental European countries, 156,000 in India, and 87,000 in Great Britain. Since 1890-91 the United States shows an increase of 1,186,600 bales, as compared with 1,205,000 in all continental European countries, 373,000 in India, and 135,000 in Great Britain.

Prices of all products entering the world's markets tend to fluctuate less and less with the development of transportation, the telegraph, the crop reporting system, and the publication of market news. Present prices are raised or lowered in anticipation of higher or lower prices in the future. This is well illustrated by the prices of cotton shown in Table XIX.

The range of prices was higher and the fluctuations were more violent in the decades 1821-30 and 1831-40, than during any other decades except that of the Civil War (1861-70). There has been a gradual diminution in the range of prices, the fluctuations being less during the decade 1881-90 than at any other period. The greatly increased crops since 1890 have depressed the price very much, causing a slightly increased range. But the tendency is towards a permanently narrow range of fluctuations.

The use of improved implements, the introduction of better methods of cultivation, the establishment of a more economical system of labour, and especially the use of fertilizers, have cheapened considerably the cost of cotton production—exactly how much, however, it is impossible to say. Until recent years no accurate records of the cost of cotton production were kept. So long as cotton brought a high price, the planters were extravagant in their methods of culture, and the factors and transportation companies excessive in their charges. The low prices of cotton which have prevailed for a number of years have taught farmers how to make cotton more economically and how to get

the full value of it after it is made, with the result that they are in better condition now to produce cotton at a steady and trustworthy profit than they ever were before.

COTTON SEED.

The history of no agricultural product contains more of interest and instruction for the student of economics than does that of cotton seed. The revolution in its treatment is a real romance of industry. Up till 1870, or thereabouts, it was regarded as a positive nuisance upon the plantation. It was left to accumulate in vast heaps about ginhouses, to the annoyance of the farmer and the injury of his premises. For cotton seed in those days was the object of so much aversion that the planter burned it or threw it into running streams, as was most convenient. If the seed were allowed to lie about, it rotted, and hogs and other small animals, eating it, often became sick and died. It was very difficult to burn, and when dumped into rivers and creeks, was carried out by flood water to fill the edges of the flats with a decaying mass of vegetable matter which gave rise to offensive odours and malaria. Although used in the early days to a limited extent as a food for milch cows and other stock, and to a larger extent as a manure, no systematic efforts were made anywhere in the South to manufacture the seed until the later 'fifties, when the first cotton seed mills were established. It is said that there were only seven cotton oil mills in the South in 1860. The cotton-growing industry was interrupted by the Civil War, and the seed-milling business did not begin again until 1868. Since that time the number of mills has been rapidly increasing. There were 25 in the South in 1870, 50 in 1880, 120 in 1890, and about 500 in 1901.

Long experience shows that 1000 pounds of seed are produced for every 500 pounds of cotton brought to market. On the basis, therefore, of a cotton crop of 10,000,000 bales of 500 pounds, there were produced in the South in 1900, 5,000,000 tons of cotton seed. About 3,000,000 tons only are pressed, producing products worth \$65,000,000 at present prices. There remains, therefore, to be utilized on the farm 2,000,000 tons of cotton seed, which, if manufactured, would produce a total of \$100,000,000 from cotton seed. In contrast with the farmers of the 'sixties, the southern planter of to-day

appreciates the value of his cotton seed, and farmers, too remote from the mills to get it pressed, now feed to their stock all the cotton seed they conveniently can, and use the residue either in compost or directly as manure. The average of a large number of analyses of whole cotton seed gives the following figures for its fertilizing constituents:—Nitrogen, 3.13 per cent.; phosphoric acid, 1.27 per cent.; potash, 1.17 per cent.; besides small amounts of lime, magnesia, and other valuable but less important ingredients. Using average prices paid for nitrogen, phosphoric acid, and potash, when bought in large quantities and in good forms, these ingredients, in a ton of cotton seed, amount to \$9.00 worth of fertilizing material. Compared with the commercial fertilizer which the farmer has to buy, cotton seed possesses therefore a distinct value.

The products of cotton seed have become important elements in the national industry of the United States. The main product is the refined oil, which is used for a great number of purposes, such as salad oil, compound lard, miners' oil, and the like. The poorer grades are employed in soap-making. Cotton seed cake or meal is one of the most valuable of feeding stuffs, as the following simple comparison between it and oats and corn will show:—

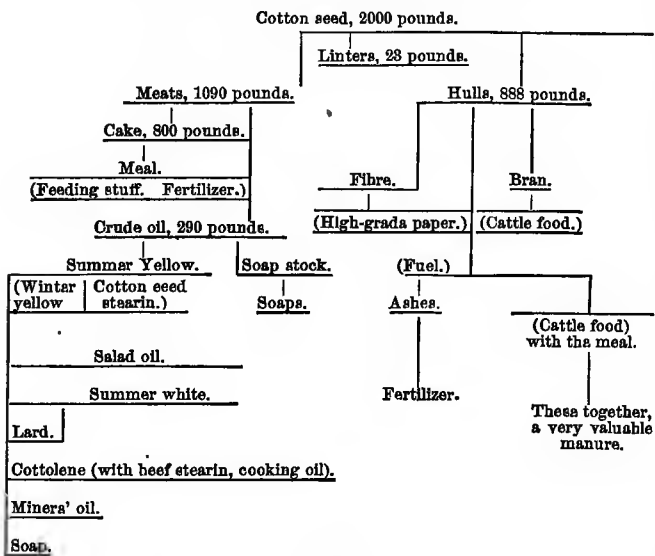

Average Analyses.	Proteins or Flesh Formers.	Carbo-hydrates or Fuel and Fat Suppliers.	Fats.	Ash or Bone Makers.
Cotton seed meal	43-26	22-31	13-45	7-02
Corn	10-5	70-0	5-5	1-02
Oats	17-0	65-0	8-0	1-2

Cotton seed meal, though poor in carbo-hydrates, the fat and energy-supplying ingredients, is exceedingly rich in protein, the nerve- and muscle-feeding ingredients. But it still contains a large amount of oil, which forms animal fat and heat, and thus makes up for part of its deficiency in carbo-hydrates. The meal, in fact, is so rich in protein that it is best utilized as a food for animals when mixed with some coarse fodder, thus furnishing a more evenly-balanced ration. In comparative valuations of feeding stuffs, it has been found that cotton seed meal exceeds corn meal by 62 per cent., wheat by 67 per cent., and raw cotton seed by 26 per cent. Cotton seed meal, in the absence of sufficient stock to consume it, is also used extensively as a fertilizer, and for this purpose it is worth, determining the price on the same basis as used above for the seed, from \$19 to \$20 per ton. But it has seldom reached this price, except in some of the Northern States, where it is used for feeding purposes. A more rational proceeding would be to feed the meal to animals and apply the resulting manure to the soil. When this is done, from 80 to 90 per cent. of the fertilizing material of the meal is recovered in the manure, only 10 to 20 per cent. being converted by the animal into meat and milk. The profit derived from the 20 per cent. thus removed is a very large one. These facts indicate that we have here an agricultural product, the market price of which is still far below its value as compared, on the basis of its chemical composition, either with other feeding stuffs or with other fertilizers. Though it is probably destined to be used even more extensively as a fertilizer before the demand for it as a feeding stuff becomes equal to the supply, practically all the cotton seed meal of the South will ultimately be used for feeding. One explanation of this condition of things is that there is still a large surplus of cotton seed which cannot be manufactured by the mills, at least under the existing arrangements for its transportation. Another reason is found in the absence of cattle in the South to eat it.

With the consideration of cotton seed oil and meal we have not, however, exhausted its possibilities. Cotton seed hulls constitute about half the weight of the ginned seed. After the seed has been passed through a fine gin, which takes off the short lint left upon it by the farmer, it is passed through what is called a sheller, consisting of a revolving cylinder, armed with numerous knives, which cut the seed in two and force the kernels from the shells. The shells and kernels are then separated in a winnowing machine. This removal of the shell makes a great difference in the oilcake, as the decorticated cake is more nutritious than the undecorticated. For a long time these shells or hulls, as they are called, were burned at oil mills for fuel, two and a half tons being held equal to a cord of wood, and four and a third tons to a ton of coal. The hulls thus burned produced an ash containing an average of 9 per cent. of phosphoric acid and 24 per cent. of potash—a very valuable fertilizer in itself, and one eagerly sought by growers of tobacco and vegetables. It was not long, however, before the stock-feeder in the South found that cotton seed hulls were an excellent substitute for hay. They are now fed on a very large scale in the vicinity of oil mills in southern cities like Memphis, New Orleans, Houston, and Little Rock, from 500 to 5000 cattle being often collected in a single yard for this purpose. No other feed is required, the only provision necessary being an adequate supply of water and an occasional allowance of salt. Many thousands of cattle are fattened annually in this way at remarkably low cost. For this purpose hulls sell at from \$2.50 to \$3 per ton.

The following diagram, modified from one by Grimshaw, in accordance with the results obtained by the better class of modern mills, gives an interesting *résumé* of the products obtained from a ton of cotton seed:—

Products from a Ton of Cotton Seed.

RICE.

Rice production in the United States is limited to that portion of the South Atlantic States nearest the sea. For two decades prior to 1861 the annual production of rice in North Carolina, South Carolina, and Georgia averaged more than 1,000,000 pounds of the clean grain. South Carolina produced over three-fourths of this. This industry was wrecked by the Civil War and has never been fully restored. From 1866 to 1880, inclusive, the annual production of these three States averaged only about 40,000,000 pounds, of which South Carolina produced one-half. Since 1880 their average annual production has been 46,000,000 pounds, of which South Carolina

produced 27,000,000. Since the Civil War the rice industry has been developing steadily in Louisiana; it averaged nearly 30,000,000 pounds for the decade 1870-80, 71,000,000 pounds in 1880-90, and obtained its greatest development in 1892, when it reached 182,000,000 pounds. The annual production is only about one-half as great as the annual consumption. The only statistics available are those made up by commercial companies, and represent only the amounts placed upon the market. The quantities consumed at home and retained for seed are considerable, but cannot be ascertained. The following table is from statistics reported by Dan Talmage's Sons Co., and gives the annual average market production of rice for the periods 1881-90 and 1891-98:—

TABLE XX.—Annual Average Market Production of Rice in the United States for the periods 1881-90 and 1891-98.

Periods.	North Carolina.	South Carolina.	Georgia.	Louisiana.	Total.
1881-90	7,185,870	28,408,940	16,919,910	71,409,961	123,869,681
1891-98	8,941,712	25,881,895	9,423,064	104,848,675	149,095,346

The annual imports of rice in the United States for 1894 to 1899 averaged 121,000,000 pounds, and the imports of broken rice, flour, and meal, 63,000,000 pounds—the whole having an average annual value of \$3,200,000.

FLAX AND HEMP.

The total number of acres devoted to the cultivation of flax for seed and fibre, both in 1889, was only 1,318,698. The production of flax seed was 10,250,000 bushels and the production of fibre 242,000 pounds. Throughout the greater portion of the flax-producing region the straw is not utilized, even for tow or for paper-making. That portion of the flax straw having a determinable value was only 207,757 tons. The total value of all flax products in 1889 was \$10,436,000. The imports of flax fibre and manufactured goods amount to from \$16,000,000 to \$18,000,000 a year, and \$2,000,000 to \$3,000,000 of this represents raw flax fibre. In consideration of these facts, the United States Department of Agriculture is making special efforts to establish the flax fibre industry in the United States. Experiments have been carried on in Minnesota, Oregon, and Washington, which indicate that flax can be successfully grown for fibre in these States. In 1860 nearly 100,000 tons of hemp (*Cannabis sativa*) were produced, while in 1895 hardly more than 5000 tons were reported for the whole country. The introduction of Manila hemp, the large importation of jute, and the decline in American shipbuilding are the reputed causes for this falling-off. The census of 1890 showed 25,000 acres in hemp, yielding 11,500 long tons, worth \$1,102,000. Nearly all of this was grown in the State of Kentucky.

TOBACCO.

The tobacco crop of 1889 amounted to 488,256,646 pounds, grown upon 695,301 acres; that of 1879 was 472,661,157 pounds, grown on 638,841 acres, which shows an increase of about 9 per cent. in acreage and 4 per cent. in products. The average yield per acre for 1879 was 738.28 pounds; for 1889, 702.22 pounds. Tobacco is grown to a greater or less extent in nearly every State and territory, the only exceptions being the northern Rocky Mountain States: but it is a commercial product in only fifteen States, which together raise 98 per cent. of the crop of the country. These fifteen States are, in the order of the weight of the crop, Kentucky, Virginia, Pennsylvania, Ohio, Tennessee, North Carolina, Maryland, Connecticut, Missouri, Wisconsin, Indiana, New York, Massachusetts, Illinois, West Virginia. Two other States, Florida and Texas, are known to have produced some cigar tobacco

since the last census was taken. In yield per acre Connecticut ranks first, with Massachusetts, Pennsylvania, New York, Wisconsin, Ohio, Missouri, and Kentucky following in the order named. In area cultivated Kentucky is first, Virginia second, North Carolina third, Tennessee fourth, Maryland fifth, Ohio sixth, Pennsylvania seventh, and Missouri eighth. There is a great difference in the annual yield per acre by weight in the different States, due not alone to the difference in soil and care in cultivation, but also to the varieties cultivated and to differences in the weather, to which the tobacco plant is extremely susceptible. Some of the lighter varieties are grown for beauty of colour and richness of flavour; other varieties are grown for bulk and weight. In the States having the

highest yield per acre, the seed leaf varieties are principally grown and high manuring practised. In Ohio and Kentucky the burly varieties are largely grown, which produce a large bulk. In North Carolina, on the other hand, the bright yellow variety is extensively raised, which gives a low yield per acre by weight. The following table (XXI.) contains statistics of tobacco production, exports, and imports, based upon information collected by the commissioner of internal revenue and the bureau of statistics of the Treasury Department. The tobacco manufactured is reported to the first-named office, and that imported and exported to the last. From these data it is possible to ascertain approximately the total crop of the country:—

TABLE XXI.—*Production of Tobacco in the United States, 1892 to 1898, as compiled from the Reports of the Bureau of Internal Revenue and of the Bureau of Statistics of the Treasury Department.*

	1892.	1893.	1894.	1895.	1896.	1897.	1898.

¹ For calendar year following.

The average amount of unmanufactured tobacco exported each year during the five years 1894-98 was 293,033,628 pounds, valued at \$24,267,718. The exports averaged 45 per cent. of the crop.

SUGAR AND MOLASSES.

The product of sugar cane, sorghum, and maple sap in 1880 and 1890 was as follows:—

Sugar Cane.

	1880.	1890.
Sugar	214,646,400	301,284,395 pounds.
Produced on	227,776	274,975 acres.
Molasses	16,573,273	25,409,228 gallons.

This is an increase of 20·72 per cent. in area under cultivation, of 40·36 per cent. in sugar, and 53·31 per cent. in merchantable molasses.

Sorghum.

	1880.	1890.
Sugar	12,792	... pounds.
Molasses	28,444,202	24,235,219 gallons.

Maple Sap.

	1880.	1890.
Sugar	36,576,071	32,952,927 pounds.
Molasses	1,796,048	2,258,376 gallons.

Cane sugar is confined almost entirely to lower Louisiana. Some cane is grown in the adjacent portions of Texas, and a little in Georgia and Florida. The following table shows the sugar product of Louisiana for the years 1895 to 1900 inclusive:—

	Tons of 2240 pounds.
1895-1896	237,720
1896-1897	232,009
1897-1898	310,447
1898-1899	245,511
1899-1900	132,000

The cane sugar of commerce has averaged 2,900,000 tons in round numbers during 1895-1900; of this all America and the West Indies produces 1,400,000 tons.

The production of sorghum molasses is about evenly distributed over the five States of Tennessee, Kentucky, Missouri, Illinois, and Iowa, with Nebraska and Kansas

as the next most important. The maple sugar product is confined to the north-western and central States. The States yielding 2,000,000 pounds, or more, each of maple sugar, are Vermont, New York, Michigan, Ohio, Pennsylvania, and New Hampshire. In 1895 only 30,000 tons of sugar were made in the United States from beets in the States of California, Nebraska, and Utah. The Department of Agriculture has recently devoted considerable attention to the culture of sugar beets, with the result that 73,000 tons of sugar were produced in 1899-1900 in these and a few other States. The total cane and beet sugar production of the world, 1899-1900, as given by the year-book of the Department of Agriculture, was 8,500,000 tons in round numbers. The United States produced 132,000 tons; Porto Rico, 50,000 tons; Cuba, 395,000 tons; the Hawaiian Islands, 275,000 tons; and the Philippine Islands (exports only), 40,000 tons, making a total of 892,000 tons for the United States and these islands.

AGRICULTURAL EDUCATION.

The agricultural schools of the United States owe their origin to the movement against the old classical school, and in favour of technical education which commenced in most civilized nations about the middle of the century. A rapidly growing country with great natural resources needed men educated in the sciences and arts of life, and this want was first manifested in the United States by a popular agitation on behalf of agricultural schools. A number of so-called agricultural schools were started between 1850 and 1860 in the eastern and middle States, where the movement made itself most felt, but without trained teachers and suitable methods they accomplished very little. They were only ordinary schools with farms attached. The first constitution of the State of Michigan, adopted in 1850, provided for an agricultural school, and this was the first one established in the United States. The General Assembly of the State of Pennsylvania incorporated the Farmers' High School, now the State College, in 1854. Maryland incorporated her agricultural

college in 1856, and Massachusetts chartered a school of agriculture in the same year. The agitation, which finally reached Congress, led to the establishment of the so-called "land-grant," or agricultural colleges. The establishment of these colleges was due chiefly to the wisdom and foresight of Justin S. Morrill, for over forty years a Representative or Senator from the State of Vermont, who introduced the first Bill for their endowment in the House of Representatives on 14th December 1857, and saw the latest one approved by the President on 30th August 1890. Mr Morrill is justly known, therefore, as the father of the American agricultural colleges. The first Act for the benefit of these colleges was entitled "An Act donating public lands to the several states and territories which may provide colleges for the benefit of agriculture and the mechanic arts," and granted to each State an amount of land equal to 30,000 acres for each senator and representative in Congress to which the State was entitled at that time. The object of the grant was stated to be "the endowment, support, and maintenance of at least one college" (in each State), "where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, . . . in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions in life." The total number of acres of land granted to the States under this Act was 9,359,241, of which 985,833 are still unsold. This grant has produced an endowment fund amounting to \$10,262,944. The lands still unsold are valued at \$4,062,850. The invested land-grant funds yield these colleges a total annual income of \$624,673. Including the United States appropriation under a Supplementary Act of 1890, commonly known as the second Morrill Act, which now gives each college \$25,000 a year, the interest on the land-grant and all other invested funds, all State appropriations and other sources of revenue, these colleges had in 1899 a total income of \$5,995,000. Sixty-four institutions have been organized under this Act, of which sixty-one maintain courses in agriculture; nineteen are departments of agriculture and engineering in State universities; twenty-seven are separate colleges of agriculture and mechanic arts; and the remainder are organized in various other ways. Separate schools for persons of African descent have been established under this Act in eight southern States. These colleges take students prepared in the common schools and give them a course of from two to four years in the sciences pertaining to agriculture. Many of them offer short courses, varying from four to twelve weeks in length, in agriculture, horticulture, forestry, and dairying, which are largely attended. Agricultural experiment stations are connected with all the colleges, and many of them conduct farmers' institutes, farmers' reading clubs, and correspondence classes.

The agricultural *Experiment Stations* of the United States grew up in connexion with the agricultural colleges. Several of the colleges early attempted to establish separate departments for research and practical experiments, on the plan of the German stations. The Act establishing the Agricultural College of Maryland required it to conduct "a series of experiments upon the cultivation of cereals and other plants adapted to the latitude and climate of the State of Maryland." This was the first suggestion of an experiment station in America, but resulted in little. The first experiment station was established at Middletown, Connecticut, in 1875, in connexion with the agricultural branch of the Sheffield Scientific School of Yale College. The State of Connecticut made in 1877 an appropriation of \$5000 to promote

agriculture by scientific investigation and experiment—the first State appropriation for this purpose. The State of North Carolina established, on 12th March 1877, an agricultural experiment and fertilizer control station in connexion with its State university. The Cornell university experiment station was organized by that institution in 1879. The New Jersey station was organized in 1880, and the station of the University of Tennessee in 1882. From these beginnings the experiment stations multiplied until, when Congress passed the National Experiment Station Act in 1887, there were seventeen already in existence. The Hatch Experiment Station Act, so called from the fact that its leading advocate was Mr William H. Hatch of Missouri, appropriated \$15,000 a year to each agricultural college for the purpose of conducting an agricultural experiment station. The object of the stations was declared to be, "to conduct original researches or verify experiments on the physiology of plants and animals; the diseases to which they are severally subject, with the remedies for the same; the chemical composition of useful plants at their different stages of growth; the comparative advantages of rotative cropping as pursued under a varying series of crops; the capacity of new plants or trees for acclimation; the analysis of soils and water; the chemical composition of manures, natural or artificial, with experiments designed to test their comparative effects on crops of different kinds; the adaptation and value of grasses and forage plants; the composition and digestibility of the different kinds of food for domestic animals; the scientific and economic questions involved in the production of butter and cheese; and such other researches or experiments bearing directly on the agricultural industry of the United States as may in each case be deemed advisable, having due regard to the varying conditions and needs of the respective States or territories." The stations were authorized to publish annual reports and also bulletins of progress for free distribution to farmers. The franking privilege was given to these publications. The office of experiment stations, in the Department of Agriculture, was established in 1888 to be the head office and clearing-house of these stations. Agricultural experiment stations are now in operation in all the States and territories. Alabama, Connecticut, New Jersey, and New York each maintains a separate station, supported wholly or in part by State funds; and Louisiana has a station for sugar experiments. Excluding all branch stations, the total number of experiment stations in the United States is fifty-six, and of these fifty-two receive the national appropriation. The total income of the stations during 1899 was \$1,143,335, of which \$720,000 was received from the National Government and the remainder was derived from societies, fees for analyses of fertilizers, sale of products, &c. The stations employ 678 persons in the work of administration and research; the chief classes being—directors, 71; chemists, 150; agriculturists, 70; horticulturists, 80; botanists, 52; entomologists, 47; physicists, 7; bacteriologists, 20; dairymen, 25; weather observers, 17; irrigation experts, 5. During 1899 the stations published 450 annual reports and bulletins, besides a large number of "press" bulletins, which are reproduced in the agricultural and county papers. The stations are to a great extent bureaus of information on all farm questions, and carry on an extensive correspondence covering all conceivable questions. Their mailing lists aggregate half a million names.

AGRICULTURAL DEPARTMENT.

The United States Department of Agriculture was established as a result of a recommendation of President

Washington, though not until many years after his death. An office for distributing seeds and collecting agricultural statistics grew up in the patent office which was originally the only scientific agency of the government. This developed gradually into the present department, which became in 1889 an executive department of the government with a secretary. This secretary is now charged with the supervision of all business relating to the agricultural and productive industries. The fisheries have a separate bureau, and the public lands and mining interests are cared for in the interior department; but with these exceptions, all the productive interests are looked after by the Department of Agriculture. There are various bureaus in this department. The weather bureau has charge of the forecasting of weather; the issue of storm warnings; the display of weather and flood signals for the benefit of agriculture, commerce, and navigation; the gauging and reporting of rivers; the reporting of temperature and rainfall conditions for the cotton, rice, sugar, and other interests; the display of frost and cold waves signals; and the distribution of meteorological information in the interest of agriculture and commerce. The bureau of animal industry makes investigations as to the existence of contagious pleuro-pneumonia and other dangerous and communicable diseases of live stock, superintends the measures for their extirpation, makes original investigations as to the nature and prevention of such diseases, and reports on the conditions and means of improving the animal industries of the country. The division of statistics collects information as to the condition, prospects, and harvests of the principal crops, and of the number and status of farm animals. It records, tabulates, and co-ordinates statistics of agricultural production, distribution, and consumption, and issues monthly and annual crop reports for the information of producers and consumers. The section of foreign markets makes investigations and disseminates information "concerning the feasibility of extending the demands of foreign markets for the agricultural products of the United States." The office of experiment stations represents the department in its relations to the experiment stations which are now in operation in all the States and territories. The division of chemistry makes investigations of the methods proposed for the analyses of soils, fertilizers, and agricultural products, and such analyses as pertain in general to the interest of agriculture. The division of entomology obtains and disseminates information regarding insects injurious to vegetation. The biological survey studies the geographic distribution of animals and plants, and maps the natural life zones of the country; it also investigates the economic relations of birds and mammals, and recommends measures for the preservation of beneficial, and the destruction of injurious species. The division of forestry is occupied with experiments, investigations, and reports dealing with the subject of forestry, and with the dissemination of information upon forestry matters. The

division of botany investigates botanical agricultural problems, including the purity and value of agricultural seeds, methods of controlling the spread of weeds or preventing their introduction into the country, &c. The division of vegetable physiology and pathology has for its object the study of the normal and abnormal life processes of plants. It seeks by investigation in the field and experiments in the laboratory to determine the causes of diseases and the best means of preventing the same. The division of agrostology is charged with the investigation of the natural history, geographical distribution, and use of grasses and forage plants, their adaptation to special soils and climates, and the introduction of native and foreign kinds into cultivation. The division of pomology collects and distributes information in regard to the fruit interest of the United States. The division of soil has for its object the investigation of the physical properties of the soils and their relation to crop production. The office of public road inquiries collects information concerning systems of road management, conducts investigations regarding the best method of road-making, and prepares publications on this subject. The division of seeds is charged with the purchase and distribution of valuable seeds, a certain portion of which are collected from foreign countries for experiments with reference to their introduction into the United States. They are distributed in allotments to senators, representatives, delegates in Congress, agricultural experiment stations, and by the Secretary of Agriculture, as provided by law.

The appropriations for the Department of Agriculture for the fiscal year ending 30th June 1899 aggregate \$2,829,702, distributed in part as follows:—

Salaries	\$319,300
Library	6,000
Museum	1,500
Animal quarantine stations	12,000
Collecting agricultural statistics	105,000
Botanical investigations and experiments	20,000
Entomological investigations	20,000
Vegetable pathological investigations	20,000
Biological investigations	17,500
Pomological investigations	9,500
Laboratory of chemistry	12,400
Forestry investigations	20,000
Experimental gardens and grounds	20,000
Soil investigations	10,000
Grass and forage plant investigations	10,000
Office of agricultural experiment station in the department ¹	40,000
Nutrition investigation	15,000
Public road inquiries	8,000
Publications	65,000
Sugar investigations	7,000
Purchase and distribution of valuable seeds	130,000
Salaries and expenses, bureau of animal industry	900,000
Irrigation	10,000
Weather bureau	1,015,502

The balance is devoted to miscellaneous current expenses.

(C. W. D.)

Aguadilla, a town on the west coast of Porto Rico, the capital of a province of the same name. It is surrounded by a fertile country producing sugar-cane, oranges, and lemons, and possesses a copious natural fountain, said to have been discovered by Columbus on his second voyage. It was founded in 1775. Population (1899), 6425.

Aguascalientes, a state of Mexico, bounded on the N., W., and E. by the state of Zacatecas, and on the S. by the state of Jalisco. Its area covers 2950 square miles. The population in 1879 was 140,430,

and in 1895, 102,378. It is divided politically into four *partidos*, subdivided into eight municipalities. The fauna embraces twenty-seven species of mammals, fifty-eight of birds, nine of reptiles, five batrachians, four fishes, and seventy-four insects. The flora includes 137 species of wild trees, forty-eight of fruit, eleven textile plants, and 103 medicinal plants, &c. The principal industries are agriculture and stock-raising. The total

¹ In addition to this amount which went to the support of the central bureau of experiment stations, \$720,000 was paid directly to agricultural experiment stations in the States by the United States Treasury.

value of the trade is estimated at about \$7,500,000 (Mexican currency). The Mexican Central railway crosses the state in two directions. The capital, AGUASCALIENTES, with a population in 1895 of 30,872, is 364 miles from the city of Mexico by rail. It has two lines of tramways, telegraph and telephone lines, schools, hospitals, public libraries, &c. The other principal towns are Rincón de Romos (or Victoria de Calpulapam), Asientos de Ibarra, and Calvillo, all with populations of less than 5000.

Aguilas, a town of Spain, province of Murcia, on the Mediterranean, 37 miles W.S.W. of Cartagena. It has two ports, one safe, the other bad. Its trade has become important, owing to the greater facilities now afforded for transport of ores by several lines of railways. In 1898, 74 foreign steamers of 70,372 tons (60 English of 58,372 tons) cleared from the port, and 120 Spanish steamers of 65,368 tons. The chief exports were: iron ore, 59,630 tons, of which 47,180 were for Great Britain; spart grass, 19,496 tons for Great Britain; and barley, soapstones, and dried figs. Population in 1897, 12,331.

Ahaggar. See SAHARA.

Ahmedabad, or AHMEDABAD, a city and district of British India, in the Gujarat division of Bombay. The city is situated on the left bank of the river Sabarmati. It is still surrounded with walls, enclosing an area of about 2 square miles. Ahmedabad has a station on the Bombay and Baroda railway, 309 miles from Bombay, whence branch lines diverge into Kathiawar and Mahi Kantha, and is a great centre for both trade and manufacture. Its native bankers, shopkeepers, and workers are all strongly organized in guilds. In 1897 there were 16 cotton-mills, for spinning and weaving, besides many hand-looms, and 14 factories for ginning and pressing cotton. Other industries include the manufacture of gold and silver thread, silk brocades, pottery, paper, and shoes. The principal educational institutions are the Gujarat College, managed by a board, with 199 students in 1896-97; a government training college for both male and female teachers, with 219 students altogether; and a high school, with 365 boys. There are 2 churches, 22 printing presses, issuing 7 newspapers and periodicals, a hospital, a lunatic asylum, an asylum for lepers, and a *panjrapol* or home of rest for animals, supported by the trading community. The military cantonment, 3 miles north of the native town, is the headquarters of the northern division of the Bombay command, with an arsenal. Population (1881), 127,621; (1891), 148,412.

The district of AHMEDABAD lies at the head of the Gulf of Cambay, between Baroda and Kathiawar. Area, 3949 square miles; population (1881), 856,342; (1891), 921,712, showing an increase of 8 per cent. and an average density of 233 persons per square mile; in 1901 the population was 795,094, showing a decrease of 14 per cent., due to the results of famine. Land revenue and rates (1897-98) amounted to Rs.23,63,780, the incidence of taxation being R.1 : 1 : 0 per acre; the cultivated area was 1,151,117 acres, of which 69,149 acres were irrigated from wells, &c., including 6142 acres from government canals; the number of police was 1098; the number of children at school was 28,795, being 3.56 per cent. of the total population; the registered death-rate in 1897 was 25.37 per thousand. The principal crops are millets, cotton, wheat, and pulse. The district is traversed by the Bombay and Baroda railway, and has two seaports, Dholera and Gogo, the former of which has given its name to a mark of raw cotton in the Liverpool market. It suffered severely in the famine of 1899-1900.

Ahmednagar, a city and district of British India, in the Deccan division of Bombay, on the left bank of the

river Sina. Several mosques and tombs have been converted to the use of British administration. The old industries of carpet-weaving and paper-making have died out; but there is a large trade in cotton and silk goods, and in copper and brass pots, and there are 9 factories for ginning and pressing cotton. It is a station on the loop line of the Great Indian Peninsula railway, 218 miles from Bombay, and a military cantonment for a native infantry regiment. It has three high schools, with 435 pupils in 1896-97, and 7 printing presses, issuing 6 vernacular newspapers. Population (1881), 37,492; (1891), 41,689.

The district of AHMEDNAGAR is a comparatively hilly and barren tract, with a small rainfall. Area, 6645 square miles; population (1881), 750,021; (1891), 888,755, showing an increase of 18 per cent. after the famine of 1876-77; average density, 134 persons per square mile; (1901), 837,774, showing a decrease of 6 per cent., due to the results of famine. In 1897-98 the land revenue and rates were Rs.19,07,825, the incidence of assessment being Rs. 2 : 1 : 2 per acre; the cultivated area was 2,585,616 acres, of which 110,246 were irrigated from wells, &c.; the number of police was 807; the children at school numbered 15,569, being 1.8 per cent. of the total population; the death-rate in 1897 was 43 per thousand. The principal crops are millets, pulse, oil-seeds, and wheat. The district suffered from drought in 1896-97, and again in 1899-1900. Down to July 1898 the deaths from plague numbered 852.

Ahmed Vefik, PASHA, (1819-1891), Turkish statesman and man of letters, was born in Stambul, 1819. He was the son of Rouheddin Effendi, at one time Chargé d'affaires in Paris, an accomplished French scholar, who because of this accomplishment was attached in the capacity of secretary-interpreter to Reshid Pasha's diplomatic mission to Paris in 1834. Reshid took Ahmed with him, and placed him at school, where he remained about five years and completed his studies. He then returned to Constantinople, and was appointed to a post in the *Bureau de traduction* of the ministry for foreign affairs. While thus employed he devoted his leisure to the translation of Molière's plays into Turkish, and to the compilation of educational books—dictionaries, historical and geographical manuals, &c.—for use in Turkish schools, with the object of promoting cultivation of the French language among the rising generation. In 1847 he brought out the first edition of the *Satnameh*, the official annual of the Ottoman empire, of which the publication is continued to this day. Two years later he was appointed imperial commissioner in the Danubian principalities, and held that office till early in 1851 when he was sent to Persia as ambassador—a post which suited his temperament, and in which he rendered good service to his Government for more than four years. Recalled in 1855, he was sent on a mission to inspect the eastern frontiers, and on his return was appointed member of the Grand Council of Justice, and was entrusted with the revision of the penal code and the code of procedure. This work occupied him until the beginning of 1860, when he was sent as ambassador to Paris, for the special purpose of averting the much-dreaded intervention of France in the affairs of Syria. But Ahmed Vefik's abrupt frankness, irascibility, and abhorrence of compromise unfitted him for European diplomacy. He offended the French Government; his mission failed; and he was recalled in January 1861. None the less his integrity of purpose was fully understood and appreciated in Paris. On his return he was appointed minister of the *Evkaf*, but he only retained his seat in the Cabinet for a few months. He was then for a brief period president of the Board of Audit, and subsequently inspector of the

Anatolian provinces where he was engaged for more than three years. His next appointment was that of director-general of customs, whence he was removed to the office of musteshar of the grand vizierate, and in the following year entered the Cabinet of Midhat Pasha as minister of public instruction, but very soon retired to his seat in the Council of State, and remained out of office until 1875 when he represented Turkey at the International Telegraphic Conference in St Petersburg. He was president of the short-lived Turkish parliament during its first session—19th March to 28th June 1877—and at its close was appointed vali of Adrianople, where he rendered invaluable aid to the Red Cross Society. On his recall at the beginning of 1878 he accepted the ministry of public instruction in the Cabinet of Ahmed Hamdi Pasha, and on the abolition of the grand vizierate (5th February 1878) he became prime minister, and held office till about the middle of April, when he resigned. Early in the following year he was appointed vali of Brusa, where he remained nearly four years, and rendered admirable services to the province. The drainage of the pestilent marshes, the water-supply from the mountains, the numerous roads, the suppression of brigandage, the multiplication of schools, the vast development of the silk industry through the substitution of mulberry plantations for rice fields, the opening out of the mineral springs of Tchitli, the introduction of rose-trees, and the production of otto of roses—all these were Ahmed Vefik's work; and he became so popular that when in 1882 he was recalled, it was thought advisable that he should be taken away secretly by night from the *konak* in Brusa, and brought to his private residence on the Bosphorus. A few days after his return he was again appointed prime minister (1st December 1882), but Ahmed Vefik demanded, as the condition of his acceptance of office, that he should choose the other members of the Cabinet, and that a number of persons in the sultan's *entourage* should be dismissed. Upon this, the sultan, on 3rd December, revoked the iradé of 1st December, and appointed Said Pasha prime minister. For the rest of his life Ahmed Vefik, by the sultan's orders, was practically a prisoner in his own house; and eventually he died, 1st April 1891, of a renal complaint from which he had long been a sufferer. Ahmed Vefik was a great linguist. He spoke and wrote French perfectly, and thoroughly understood English, German, Italian, Greek, Arabic, and Persian. From all these languages he translated many books into Turkish, but wrote no original work. His splendid library of 15,000 volumes contained priceless manuscripts in many languages. In his lifetime he appreciably aided the progress of education; but, as he had no following, the effects of his labour and influence in a great measure faded away after his death. In all his social and family relations Ahmed Vefik was most exemplary. His charity knew no bounds. He was devoted to his aged mother and to his one wife and children. To his friends and acquaintances he was hospitable, courteous, and obliging; his conversation was intellectual and refined, and in every act of his private life he manifested the spirit of a true gentleman. At home his habits, attire, and mode of life were quite Turkish, but he was perfectly at his ease in European society; he had strong English proclivities, and numbered many English men and women amongst his intimate friends. In public life his gifts were almost sterilized by peculiarities of temperament and incompatibility with official surroundings; and his mission as ambassador to Persia and his administration of Brusa were his only thorough successes. But his intellectual powers, literary erudition, and noble character made him for the last forty years of his life a conspicuous figure in Eastern Europe.

(E. W.*)

Ahvaz, a town in the province of Arabistan, Persia, situated on the left bank of the river Karun, has been identified with the Aginis of Nearch. It is now a wretched collection of mud hovels, with a small rectangular fort in a state of ruin, and an Arab population of about 700. Since the opening of the Karun to foreign commerce in October 1888 another settlement called *Bander i Nássiri*, in compliment to the shah (Nássir ed dín), has been established on a slight elevation overlooking the river at the point near the rapids, where steamers come to anchor, and about one mile below Ahvaz. It has post and telegraph offices, and a few mercantile firms have established agencies at Bander Nássiri. Should the new caravan road to Isfahan prove a success, Ahvaz will no doubt soon acquire greater commercial importance.

Aidin, (1) a Turkish viláyet, in the S.W. part of Asia Minor, which includes the ancient Lydia, Caria, and Western Lycia. It derives its name from the Seljúk emir who took Tralles, and is the richest and most productive province of Asiatic Turkey. The seat of government is Smyrna. Population, 1,400,000 (Moslem, 1,090,000; Christians, 288,000; Jews, 22,000). (2) The principal town of the rich, productive valley of the Menderez, called also Güzelhissar from the beauty of its situation at the foot and on the lower slopes of *Mons Messogis*. Aidin is on the Smyrna-Dineir railway, has large tanneries, and sweetmeat manufactories, and exports figs, cotton, and raisins. It was almost destroyed by an earthquake in 1899. It is the seat of a British vice-consul. Population, 34,000 (Moslems, 23,000; Christians, 9000; Jews, 2000).

Aigun, or AIHUN (also *Sakhalyan-ula-khoto*), a town of China, province Hei-lun-tsián, in Northern Manchuria, situated on the right bank of the Amur, in a fertile and populous region, 20 miles below Blagovyeshchensk, where it occupies nearly two miles on the bank of the river. There is a palisaded fort in the middle of the town, inside of which is the house of the *fu-tu-fun* (governor). Its merchants carry on an active local trade in grain, mustard, oil, and tobacco, and some of its firms supply the Russian administration with grain and flour. During the "Boxer" rising of 1900 it was, for a few weeks, the centre of military action directed against the Russians. The population, of some 20,000, includes a few hundred Musulmans. The town was founded first on the left bank of the Amur, below the mouth of the Zeya, but was abandoned, and the present town was founded in 1684. It was here that Count Muravieff concluded, in May 1857, the Aihun treaty, according to which the left bank of the Amur was conceded to Russia.

Ain, a department in the E. of France, bordering on Switzerland. Its eastern part is traversed by the southern end of the Jura. The Rhône enfolds it on the E. and S., the Saône forms its western border; the Ain runs through its centre from N. to S. into the Rhône. Among the lacustrine formations is Lake Nantua. The chief towns are Bourg, Belley, Gex, Nantua, and Trévoux.

Area, 2249 square miles. The department comprises 36 cantons and 468 communes. Population in 1896, 351,569, against 364,408 in 1886. Births in 1899, 7204, of which 362 were illegitimate; deaths, 7204; marriages, 2665. In 1896 there were 1063 primary schools, with 57,502 pupils. Less than 1 per cent. of the population was illiterate. The total surface under cultivation was 1,236,173 acres, of which 601,744 acres were plough-land; 229,786 acres in grass, and 265,772 acres in forest. In 1899 the produce of wheat amounted to the value of £1,025,000; of wine, £405,000. There were (1899) 14,260 horses, 3080 asses and mules, 240,190 cattle, 50,720 sheep, 87,030 pigs, and 20,190 goats. The mineral production (lignite, peat, and other substances) is unimportant. There is no industry in metals. With agriculture, the industries in weaving, wearing apparel, foods, and the manufacture of paper, are the sources of the prosperity of Ain.

Ainsworth, William Harrison (1805-1882), English novelist, son of Thomas Ainsworth, solicitor, was born at Manchester, 4th February 1805. He was educated at Manchester Grammar School, and articled to the firm of which his father was a member, proceeding to London in 1824 to complete his legal training at the Inner Temple. At the age of twenty-one he married a daughter of John Ebers, the publisher, and started in his father-in-law's line of business. This, however, soon proved unprofitable, and he decided to attempt literary work. A novel called *Sir John Chiverton*, in which he appears to have had a share, had attracted the praise of Sir Walter Scott, and this encouragement decided him to take up fiction as a career. In 1834 he published *Rookwood*, which had an immediate success, and thenceforth he was always occupied with the compilation of "historical" novels. He published about forty such stories, of which the best known are *Jack Sheppard* (1839), *The Tower of London* (1840), *Guy Fawkes* (1841), *Old St Paul's* (1841), and *Windsor Castle* (1843). He edited *Bentley's Miscellany*, in which *Jack Sheppard* was published as a serial, and for twelve years from 1842 he was proprietor of *Ainsworth's Magazine*. He continued his literary activity until his death, but his later stories were less striking than the earlier, perhaps owing to his having exhausted the more fruitful fields of historical narrative in his first flights. He died at Reigate, 3rd January 1882, and was buried at Kensal Green. Ainsworth had a lively talent for plot, and his books have many attractive qualities. He was skilful in weaving historical facts into the fabric of fiction, and in giving just sufficient of the former to leaven the latter with an air of probability. His style was not without archaic affectation and awkwardness, but when his energies were aroused by a striking situation he could be brisk, vigorous, and impressive. He did a great deal to interest the less educated classes in the historical romances of their country, and his tales were invariably instructive, clean, and manly. (A. WA.)

Aintab, mediæval *Hamtab*, a large garrison town in Syria, in the Aleppo vilâyet, situated in the broad valley of the Sajûr. Its position is one of military and commercial importance, and its castle was noted in the Middle Ages for its great strength. In 1895 many Armenians were massacred and the bazars were pillaged. American missionary and educational enterprise has established Central Turkey College, with a medical school, a girls' school and an hospital. Cereals and tobacco are exported, and cotton cloths are made. Population, 45,000 (Moslems, 26,000; Christians, 18,500; Jews, 500).

Ainu.—The Ainu—often erroneously called Aino—are usually spoken of as the autochthonous inhabitants of Japan, but the most accurate researches go to prove that they were immigrants, who reached Yezo from the Kuriles, and subsequently crossing Tsugaru strait, colonized a great part of the main island of Japan, exterminating a race of pit-dwellers to whom they gave the name of *koro-pok-guru* (men with sunken places). These *koro-pok-guru* were of such small stature as to be considered dwarfs. They wore skins of animals for clothing, and that they understood the potter's art and used flint arrow-heads is clearly proved by excavations at the sites of their pits. The Ainu, on the contrary, never had any knowledge of pottery. Ultimately the Ainu, coming into contact with the Japanese, who had immigrated from the south and west, were driven northward into the island of Yezo, where, as well as in the Kuriles and in the southern part of Saghalien, they are still found in some numbers. When, at the close of the 18th and the beginning of the 19th century, Russian enterprises drew the attention of

the Japanese Government to the northern districts of the empire, the Tokugawa Shoguns adopted towards the Ainu a policy of liberality and leniency consistent with the best principles of modern colonization. But the doom of unfitness appears to have begun to overtake the race long ago. History indicates that in ancient times they were fierce fighters, able to offer a stout resistance to the incomparably better armed and more civilized Japanese. To-day, they are drunken, dirty, spiritless folk, whom it is difficult to suppose capable of the warlike rôle they once played. Their number is virtually stationary, as the census shows:—

Ainu Population of Yezo and the Kuriles.

1893	17,280
1894	15,308
1895	17,314
1896	17,400
1897	16,972
1898	17,573

The Ainu are somewhat taller than the Japanese, stoutly built, well proportioned; with dark-brown eyes, high cheek-bones, short broad noses and faces lacking length. Naturally very hairy and never shaving after a certain age, they have full beards and moustaches. Men and women alike cut their hair level with the shoulders at the sides of the head, but trim it semicircularly behind. The women tattoo their mouths, arms, and sometimes their foreheads, using for colour the smut deposited on a pot hung over a fire of birch bark. Their original dress is a robe spun from the bark of the elm tree. It has long sleeves, reaches nearly to the feet, is folded round the body and tied with a girdle of the same material. Females wear also an undergarment of Japanese cloth. In winter, the skins of animals are worn, with leggings of deer-skin and boots made from the skin of dogs or salmon. Both sexes are fond of ear-rings, which are said to have been made of grape-vine in former times, but are now purchased from the Japanese, as also are bead necklaces, which the women prize highly. Their food is meat, whenever they can procure it—the flesh of the bear, the fox, the wolf, the badger, the ox, or the horse—fish, fowl, millet, vegetables, herbs, and roots. They never eat raw fish or flesh, but always either boil or roast it. Their habitations are reed-thatched huts, the largest 20 feet square, without partitions and having a fireplace in the centre. There is no chimney, but only a hole at the angle of the roof; there is one window on the eastern side and there are two doors. Public buildings do not exist, whether in the shape of inn, meeting-place, or temple. The furniture of their dwellings is exceedingly scanty. They have no chairs, stools, or tables, but sit on the floor, which is covered with two layers of mats, one of rush, the other of flag; and for beds they spread planks, hanging mats around them on poles, and employing skins for coverlets. The men use chop-sticks and moustache-lifters when eating; the women have wooden spoons. Uncleanliness is characteristic of the Ainu, and all their intercourse with the Japanese has not improved them in that respect. The Rev. Mr Batchelor, in his *Notes on the Ainu*, says that he lived in one Ainu habitation for six weeks on one occasion, and for two months on another, and that he never once saw personal ablutions performed, or cooking or eating utensils washed. Not having been at any period acquainted with the art of writing, they have no literature and are profoundly ignorant. But at schools established for them by the Japanese in recent times, they have shown that their intellectual capacity is not deficient. No distinct conception of a universe enters into their cosmology. They picture to themselves many floating worlds, yet they deduce the idea of rotundity from the course of the sun, and they imagine that the "Ainu world"

rests on the back of a fish whose movements cause earthquakes. It is scarcely possible to doubt that this fancy is derived from the Japanese, who used to hold an identical theory. They believe in a supreme Creator, but also in a sun god, a moon god, a bear god, a water god, and a mountain god; deities whose river is the Milky Way, whose voices are heard in the thunder and whose glory is reflected in the lightning. They have no priests by profession. The village chief performs whatever religious ceremonies are necessary; ceremonies confined to making libations of wine, uttering short prayers and offering willow sticks with wooden shavings attached to them, much as the Japanese set up the well-known *gohet* at sacred spots. The Ainu gives thanks to the gods before eating, and prays to the deity of fire in time of sickness. He thinks that his spirit is immortal, and that it will be rewarded hereafter in heaven or punished in hell, both of which places are beneath the earth, hell being the land of volcanoes; but he has no theory as to a resurrection of the body or metempsychosis. He preserves a tradition about a flood which seems to be the counterpart of the Biblical deluge, and about an earthquake which lasted a hundred days, produced the three volcanoes of Ezo, and created the island by bridging the waters that had previously separated it into two parts. He is now governed by Japanese laws and judged by Japanese tribunals, but in former times his affairs were administered by hereditary chiefs, three in each village, and for administrative purposes the country was divided into three districts, Sara, Usu, and Ishikari, which were under the ultimate control of Sara, though the relations between their respective inhabitants were not close and intermarriages were avoided. The functions of judge were not entrusted to these chiefs; an indefinite number of a community's members sat in judgment upon its criminals. Capital punishment did not exist, nor was imprisonment resorted to, beating being considered a sufficient and final penalty, except in the case of murder, when the nose and ears of the assassin were cut off or the tendons of his feet severed. These peculiar methods of criminal procedure are alluded to by ancient Japanese historians, who appear to have regarded them as more barbarous than infliction of the death penalty. Little as the Japanese and the Ainu have in common, intermarriages are not infrequent, and at Sambutsu especially, on the eastern coast, many children of such marriages may be seen. Doenitz, Hilgen-dorf, and Scheube, arguing from a minute investigation of the physical traits of the Ainu, have concluded that they are "Mongolians who differ less, perhaps, from the Japanese than the Germans do from the Rumanians," but if their customs, traditions, and religious beliefs be considered, the points of dissimilarity are very striking. According to Professor A. H. Keane, the Ainu "are quite distinct from the surrounding Mongolic peoples, and present several remarkable physical characters which seem to point to a remote connexion with the Caucasian races. Such are a very full beard, shaggy or wavy black or dark-brown hair, sometimes covering the back and chest; a somewhat fair or even white complexion, large nose, straight eyes, and regular features, often quite handsome,

and of European type. They seem to be a last remnant of the Neolithic peoples, who ranged in prehistoric times across the northern hemisphere from the British Isles to Manchuria and Japan. They are bear-worshippers, and have other customs in common with the Manchurian aborigines, but the language is entirely different, and they have traditions of a time when they were the dominant people in the surrounding lands." It should be noted finally that the Ainu are altogether free from ferocity or exclusiveness, and that they treat strangers with gentle kindness. (F. BY.)

Airdrie, a parliamentary and municipal burgh (Falkirk group) in new Monkland parish, Lanarkshire, Scotland, 10 miles E. of Glasgow by rail. There are 35 coal mines in the parish, but the seams are now largely worked out. Brass-founding, steel-casting, tube-making, boiler-making, wagon-building, the weaving of woolsens, calico-printing, paper-making, and oil and fire-clay manufacture, are now important, while several new branches of engineering have been started. There is a good free library. One of the board schools is an academy or secondary school. Population in 1881, 13,363; 1891, 19,135; 1901, 22,288.

Air Gun.—Air as a propellant has in recent years been applied to guns of large calibre, in which its comparatively gentle action has proved advantageous when high explosives contained in their shells are employed as projectiles. In 1883 Mr. Mefford of Ohio utilized an air pressure of 500 lb per square inch in a 2-inch gun, and succeeded in propelling a projectile 2100 yards. The arrangement was of the simplest form—a hose with an ordinary cock by which the air was admitted into the gun behind the projectile. The question was then taken up by Captain E. L. Zalinski of the United States Artillery, who in 1888 reduced the so-called "dynamite gun" to a practical shape and obtained excellent firing results.

The principal features of his system are:—1. An extremely ingenious balanced valve admitting the air pressure into the gun. This valve is opened and closed by a simple movement of the firing lever, and is capable of adjustment so that the propelling force, and consequently the range, can be regulated. 2. A light steel projectile carrying the bursting charge, and provided with a tail

DYNAMITE GUN MOUNTED AT SANDY HOOK, NEW YORK HARBOUR.

to which vanes are attached in order to give rotation. 3. Electric fuses of entirely original design. Each shell carries a wet battery, the current from which fires the charge on impact with any solid object, and a dry battery which becomes active after the shell has dived below the surface of the water, and ignites the charge after delay capable of regulation. For safety all the electric circuits are made to pass through a disconnecter, which prevents them from being completed until the shell has been fired. The gun is a built-up

smooth-bore tube, 15 inches or less in diameter. The full-calibre shell weighs 1000 lb, and carries a bursting charge of 600 lb of blasting gelatine, cut into the form of cheeses, fitting the steel envelope, and provided with a core of dry gun-cotton as a primer. Sub-calibre projectiles, 10 in. and 8 in., can also be used. In their case, rotation is given by vanes or fins attached to the body of the shell. Air at 1000 lb pressure is stored in tubes close to the gun, and is supplied from primary reservoirs, to which it is directly pumped at a pressure of about 2000 lb. There is always, therefore, a considerable reserve of power available without pumping. Pneumatic guns of this description (see figure) have been mounted for the protection of New York and San Francisco. With a full-calibre shell (1000 lb) these guns have a range of 2400 yards; with a sub-calibre 8-in. shell (250 lb) the maximum range is 6000 yards. The official trials showed remarkable accuracy. At 6000 yards 75 per cent. of the projectiles fell in an area of 360×90 feet. When the gun was tried at Shoeburyness the accuracy was far greater than could be obtained with howitzer shells propelled by explosives. - On account of the power of exploding the shell under water, and thus securing a torpedo action, a direct hit upon a ship is not required, and the target offered is largely in excess of the deck plan. The gun is, in fact, capable of replacing systems of submarine mines with economy, and without the great objection of interfering with a waterway.

The only employment of the dynamite gun afloat has been in the case of the U.S.A. gunboat *Vesuvius*, which carries three in the bows. These guns are fixed at a constant angle of elevation, and the range is regulated by the air valve, training being given by the helm. Thus mounted on an unstable platform, the accuracy of fire obtainable must evidently be much less than on shore. The *Vesuvius* was employed during the Spanish-American war of 1898, when on several nights in succession she approached the defences of Santiago, under cover of darkness and discharged three projectiles. Fire delivered under such conditions could not be sufficiently accurate to injure coast defences; but the shells burst well, and made large craters. (G. S. C.)

Airy, Sir George Biddell (1801-1892), British Astronomer Royal, was born at Alnwick on 27th July 1801. He came of a long line of Airys who traced their descent back to a family of the same name residing at Kentmere, in Westmoreland, in the 14th century, but the branch to which he belonged, having suffered in the civil wars, removed to Lincolnshire, where for several generations they lived as farmers. George Airy was educated first at elementary schools in Hereford, and afterwards at Colchester Grammar School. In 1819 he entered Trinity College, Cambridge, as a sizar. Here he had a most brilliant career, and seems to have been almost immediately recognized as the leading man of his year. In 1822 he was elected scholar of Trinity, and in the following year he graduated as senior wrangler and obtained first Smith's prize. On 1st October 1824 he was elected fellow of Trinity, and in December 1826 was appointed Lucasian Professor of Mathematics in succession to Turton. This chair he held for little more than a year, being elected in February 1828 as Plumian Professor of Astronomy and director of the new Cambridge observatory. Some idea of his activity as a writer on mathematical and physical subjects during these early years may be gathered from the fact that previous to this appointment he had contributed no less than three important memoirs to the *Philosophical Transactions of the Royal Society*, and eight to the Cambridge Philosophical Society. At the Cambridge observatory Airy soon gave evidence of his remarkable power of organization. At the time of his appointment the only telescope erected in the observatory was the transit instrument, and to this he devoted himself with vigour. By the introduction of a regular system of selection and arrangement of his observations, and a carefully worked out plan of reduction, he was able to keep his observations reduced practically up to date and published annually with a degree of punctuality which

astonished his contemporaries. Under his direction a mural circle was soon erected, and regular observations were instituted with it in 1833. In the same year the duke of Northumberland presented the Cambridge observatory with a fine object glass of 12 inches' aperture, which was mounted according to Airy's designs and under his superintendence, although the erection was not completed until after his removal to Greenwich in 1835. Airy's writings during this time are divided between mathematical physics and astronomy. The former are for the most part concerned with questions relating to the theory of light, arising out of his professorial lectures, among which may be specially mentioned his paper "On the Diffraction of an Object-Glass with Circular Aperture." In 1831 the Copley medal of the Royal Society was awarded to him for these researches in optics. Of his astronomical writings during this period the most important are his investigation of the mass of Jupiter, his report to the British Association on the progress of astronomy during the 19th century, and his memoir *On an Inequality of Long Period in the Motions of the Earth and Venus*. His report is remarkable for the conciseness and accuracy with which the condition of the science at the time is exhibited. The last section but one of this report is devoted to "A Comparison of the Progress of Astronomy in England with that in other Countries," very much to the disadvantage of England. This reproach was subsequently, to a great extent, removed by his own labours.

Airy's discovery of a new inequality in the motions of Venus and the earth is in some respects his most remarkable achievement. In correcting the elements of Delambre's solar tables he had been led to suspect an inequality not embraced by those tables. For the cause of this he did not long seek in vain. Eight times the mean motion of Venus is so nearly equal to thirteen times that of the earth that the difference amounts to only the $1/240$ th of the earth's mean motion, and from the fact that the term depending on this difference, although very small in itself, receives in the integration of the differential equations a multiplier of about 2,200,000, Airy was led to infer the existence of a sensible inequality extending over 239 years. The investigation by which this result was established was probably the most laborious that had been made up to Airy's time in the planetary theory, and was the first specific improvement in the solar tables made in England since the establishment of the theory of gravitation. In recognition of this work the medal of the Royal Astronomical Society was awarded to him in 1833.

In June 1835 Airy was appointed Astronomer Royal in succession to Pond, and thus commenced that long career of wisely directed and vigorously sustained industry at the National Observatory which, even more perhaps than his investigations in abstract science or theoretical astronomy, constitutes his chief title to fame. The state of the observatory at the time of his appointment was such that Lord Auckland, the first lord of the Admiralty, considered that "it ought to be cleared out," while Airy admits that it "was in a queer state." With his usual energy he set to work at once to reorganize the whole management. He remodelled the volumes of observations, the library was put on a proper footing, the new (Sheepshanks) equatorial was erected, and a new magnetic observatory was built. In 1847 the altazimuth, designed by Airy to enable observations of the moon to be made whenever she might be visible (and not only on the meridian), was constructed. In 1848 Airy invented the reflex zenith tube to take the place of the zenith sector which had been employed up to that time. At the end of 1850 the great transit circle of 8 in. aperture and 11 ft. 6 in. focal length S. I. — 30

was erected; this telescope is still the principal instrument of its class at the observatory. And finally, in 1859, a large equatorial of 13 in. aperture was erected. In his journal for that year he remarks, "There is not now a single person employed or instrument used in the observatory which was there in Mr Pond's time."

The great work of reducing the accumulated planetary observations made at Greenwich from 1750 to 1830 had been already commenced and was in progress when Airy became Astronomer Royal. Shortly afterwards he undertook the further laborious task of reducing the enormous mass of observations of the moon made at Greenwich during the same period under the direction, successively, of Bradley, Bliss, Maskelyne, and Pond, to defray the expense of which a large sum of money was allotted by the Treasury. The immediate result of this work, which was not completed till 1846, was to rescue from oblivion no less than 8000 observations of the moon, and to place them at the disposal of astronomers in such a form that they could be used directly for comparison with the theory and for the improvement of the tables of the moon's motion. For this work Airy received a testimonial from the Royal Astronomical Society in 1848. The first-fruit of this work was soon seen in the discovery by Prof. Hansen, of Seeburg in Gotha, of two new inequalities in the moon's motion. After completing this labour, and before engaging in any theoretical investigation in connexion with it, Airy made inquiries whether any other mathematician was pursuing the same subject, and learning that Prof. Hansen had undertaken this problem under the patronage of the king of Denmark, but that, owing to the death of the king, it was in danger of falling through for lack of funds, he applied to the Admiralty for the sum required to enable Prof. Hansen to complete his work. This request was immediately granted, and thus it comes about that Hansen's famous *Tables de la Lune* are dedicated to *La Haute Amiralauté de sa Majesté la Reine de la Grande Bretagne et d'Irlande*.

One of the most remarkable of Airy's researches is his determination of the mean density of the earth. In 1826 the idea occurred to him of attacking this problem by means of pendulum experiments at the top and bottom of a deep mine. His first attempt, made in the same year, at the Dolcoath mine in Cornwall, failed in consequence of an accident to one of the pendulums; a second attempt in 1828 was defeated by a flooding of the mine, and many years elapsed before another opportunity presented itself. The experiments eventually took place at the Harton pit near South Shields in 1854. The immediate result of the experiment was to show that gravity at the bottom of the mine exceeded that at the top by $1/192866$ th of its amount, the depth being 1256 feet. From this he was led to the final value of 6.566 for the mean density of the earth as compared with that of water. This value is considerably in excess of that previously found by other methods, but from the care and completeness with which the observations were carried out and discussed, it is, as Airy himself says, "entitled to compete with the others on, at least, equal terms."

In 1872 Airy conceived the idea of treating the lunar theory in a new way, and at the age of seventy-one he embarked on the prodigious labour which this scheme entailed. A general description of his method will be found in the *Monthly Notices of the Royal Astronomical Society*, vol. xxxiv. No. 3. His method consisted essentially in the adoption of Delaunay's final numerical expressions for longitude, latitude, and parallax, with a symbolic term attached to each number, the value of which was to be determined by substitution in the equations of motion. In this mode of treating the question the order of the terms is numerical, and though the

amount of labour is such as might well have deterred a younger man, yet the details were easy, and a great part of it might be entrusted to a mere computer. This work was published in 1886, when its author was eighty-five years of age. For some little time previously he had been harassed by a suspicion that certain errors had crept into the computations, and accordingly he addressed himself to the task of revising his work. But his powers were no longer what they had been, and he was never able to examine sufficiently into the matter. In 1890 he tells us how a grievous error had been committed in one of the first steps, and pathetically adds, "My spirit in the work was broken, and I have never heartily proceeded with it since." In 1881 Sir George Airy resigned the office of Astronomer Royal and resided at the White House, Greenwich, not far from the Royal Observatory, until his death, which took place on 2nd January 1892.

A complete list of Airy's printed papers, numbering no less than 518, will be found in his *Autobiography*, edited by his son, Wilfrid Airy, B.A., M.Inst.C.E. Amongst the most important of his works not already mentioned may be named the following:—*Mathematical Tracts* (1826) on the *Lunar Theory*, *Figure of the Earth*, *Precession and Nutation*, and *Calculus of Variations*, to which, in the second edition of 1828, were added tracts on the *Planetary Theory*, and the *Undulatory Theory of Light*; *Experiments on Iron-built Ships, instituted for the purpose of discovering a correction for the deviation of the Compass produced by the Iron of the Ships* (1839); *On the Theoretical Explanation of an apparent new Polarity in Light* (1840); *Tides and Waves* (1842).

He was elected a fellow of the Royal Society in 1836 and president in 1871, and received both the Copley and Royal medals. He was five times president of the Royal Astronomical Society, was correspondent of the French Academy, and belonged to many other foreign and American societies. He was D.C.L. of Oxford, and LL.D. of Cambridge and Edinburgh. In 1872 he was made K.C.B. In the same year he was nominated a Grand Cross in the Imperial Order of the Rose of Brazil; he also held the Prussian Order "Pour le Mérite," and belonged to the Legion of Honour of France, and to the Order of the North Star of Sweden and Norway. (A. A. R.*)

Aisne, a department in the N.E. of France. The northern part is crossed by branches of the Ardennes. The country is watered by the Somme, the Escaut, the Sambre, the Oise, the Aisne, and the Marne.

Area, 2868 square miles. The department comprises 87 cantons and 841 communes, and its population in 1901 numbered 535,583, against 555,925 in 1886. The chief towns are Laon, the capital of the department, Château-Thierry, St Quentin, with important industries and 48,868 inhabitants in 1896, Soissons, and Vervins. Births in 1899, 12,164, of which 1450 were illegitimate; deaths, 12,077; marriages, 4251. In 1896 there were 1363 primary schools, with 76,645 pupils. Eight per cent. of the population was illiterate. Agriculture is highly developed, 1,717,107 acres being under cultivation in 1896, of which 1,197,950 acres were plough-land, 210,274 acres forest, and 197,688 acres in grass. In 1899 the produce of wheat was valued at £1,960,120; rye at £176,000; oats at £983,240. The production of mangold-wurzel and of potatoes is also considerable. The production of beetroot (1899) exceeded 26,000,000 hundredweights, placing the department second in this respect. The live stock numbered (1899) 781,060, of which 77,870 were horses. The value of milk products in 1899 was £1,012,000. There are no metals in the department of Aisne, but there is abundance of building-stone and of brick-clay. The industries of Aisne are weaving, St Quentin being renowned for its cambrics; plate-glass manufacture (St Gobain); glass-making (Folembray); but especially sugar-refining. With a production in 1899 of 171,000 tons, involving the labour of 10,500 men and women, Aisne takes the lead of all the departments of France in the sugar industry.

Aitaluki. See COOK ISLANDS.

Aivali, a prosperous town on the west coast of Asia Minor, opposite the island of Mitylene. It stands, near the site of the *Æolian Heracleia*, on rising ground at the end of a bay which is separated from the Gulf of Adramyttium, and protected from the prevailing winds by the Muskonesi Islands (*Hecatonnesoi*). In 1821 it was burned to the ground during a fight between the Turks and the Greeks, and a large number of its Greek population killed or enslaved. It is now one of the most thriving towns in the Levant, with a purely Greek population distinguished for its commercial, industrial, and maritime enterprise. The exports are olive oil, soap, and raki; and a fleet of fishing-boats supplies Constantinople and Smyrna with fish; the exports in 1899 were valued at £944,743, and the imports at £286,425. It is the seat of a British vice-consulate. Population, 36,000.

Aix-la-Chapelle, German *Aachen*, a town and watering-place of Prussia, in the Rhine prov., between the Meuse and the Rhine, 44 miles W.S.W. from Cologne by the railway to Liège. It possesses more than thirty churches, besides the cathedral. A handsome building was put up in 1886-89, behind the façade (1267) of the old town hall, to accommodate the archives. The Suermond museum contains collections of antiquities, pictures, arms, and industrial art objects. There are two or three technical schools, a commercial college, a commercial high school (opened in 1898), a deaf and dumb asylum, lunatic asylums, a teachers' seminary, a polytechnic, a technical high school, and a newspaper museum. In the vicinity are coal-mines employing about 9000 men. This city is the seat of a very active commerce in cereals, timber, leather, coal, metals, wool, wine, &c. In 1897 the town of BURTSCHIED was incorporated with Aix-la-Chapelle. Burtscheid also has thermal baths (140° to 160° Fahr.), and carries on the same industries as Aix-la-Chapelle. Population (1885), 95,725; (1895), 110,551; (1901), 135,235.

Ajaccio, the chief town of the island of Corsica, a department of France, stands on the west side of the island. It lies 676 miles S.E. of Paris, and is the terminal station of railways from Bastia and Calvi. The library (35,000 volumes), a fine collection of pictures, and a communal college, all now in the Palais Fesch, were founded by the cardinal of that name, half-brother of Napoleon's mother. The culture of the citron has greatly extended in recent years, and gallic acid is now an important export. The Citadelle harbour affords good anchorage, but the port accommodation is indifferent. The total length of quays is 2000 feet, with a depth alongside of from 9 to 22 feet. In 1899, 640 vessels of 213,370 tons entered, and 650 of 214,107 tons cleared. Population (1881), 15,351; (1891), 17,248; (1896), 17,398, (comm.) 18,553; (1901), 21,779.

Ajaigarh, a native state of India, in Bundelkhand, under the Central India agency; lying between 24° 45' and 24° 58' N. lat., and between 80° 4' and 80° 22' E. long. It has an area of 802 square miles; and a population of 93,048, being 116 persons per square mile. The chief, who is a Bundela Rajput, bears the title of Sawai Maharaja. He has an estimated revenue of about Rs.2,25,000, and pays a tribute of Rs.7010. He resides at the town of Naushahr, at the foot of the hill-fortress of Ajaigarh, from which the state takes its name. The state suffered severely from famine in 1868-69, and again in 1896-97.

Ajmer, a city of British India, in Rajputana, which gives its name to a district and also to a petty province called Ajmer-Merwara; situated in 26° 27' N. lat. and 74° 44' E. long., on the lower slopes of Taragarh Hill, in the Aravalli Mountains. It is an important station on the Rajputana

railway, 615 miles from Bombay and 275 miles from Delhi, with a branch running due south to the Great Indian Peninsula main line. The city is well laid out, with wide streets and handsome houses. It is still surrounded by a stone wall. The educational institutions include a college, with 212 students in 1897-98, and the Mayo Rajkumar College, opened in 1875, for training the sons of the nobles of Rajputana on the lines of an English public school, with 63 pupils in 1897-98, maintained at a total cost of Rs.47,479. Population (1867), 34,763; (1881), 48,735; (1891), 68,843; (1901), 75,759, showing an increase of 10 per cent. The district of AJMER, which forms the larger part of the province of Ajmer-Merwara, has an area of 2070 square miles. Population (1891), 422,359, being 204 persons per square mile; (1901), 366,800, showing a decrease of 13 per cent. Besides the city of Ajmer, it contains the military station of Nasirabad; population, 21,710.

Ajmer-Merwara, a division or petty province of British India, in Rajputana, consisting of the two districts of Ajmer and Merwara, separated from each other and isolated amid native states. The administration is in the hands of a commissioner, subordinate to the governor-general's agent for Rajputana. The capital is Ajmer city. The area is 2711 square miles. The population in 1891 was 542,358, being 200 persons per square mile, the classification according to religion being: Hindus, 437,988, or 81 per cent.; Mahomedans, 74,265, or 13 per cent.; Jains, 26,939, or 5 per cent.; Christians, 2683; and "others," 483; in 1901 the population was 476,330, showing a decrease of 12 per cent., due to the results of famine. Among Hindus, the Rajputs are landholders, and the Jats and Gujars are cultivators. The Jains are traders and money-lenders. The aboriginal tribe of Mers are divided between Hindus and Mahomedans. In 1897-98 the total cultivated area was returned at 404,413 acres, of which 62,305 acres were twice cropped. The chief crops are millet, wheat, cotton, and oil-seeds. The irrigated area was 142,287 acres, of which 107,677 were irrigated from wells, and 33,955 from tanks. The land revenue was Rs.4,42,526, being at the rate of R.1:3:11 per cultivated acre, and 14 annas per head of population. The total number of schools was 192, with 10,771 pupils; and the total expenditure on education was Rs.92,463. There are 12 factories for ginning and pressing cotton, the chief trading centres being Beawar and Kekri. Together with the surrounding country, Ajmer-Merwara suffered very severely from the famine of 1899-1900. In June 1900 the number of persons in receipt of relief was 143,000, being more than one-fourth of the total population.

'Akabah, Gulf of, the classical *Ælaniticus Sinus*, from the town of *Ælana* at its head; a continuation southward of the Jordan-Araba depression. Raised beaches on the coast show that there has been an elevation of the sea-bed of 200 feet. Near the head of the gulf is Jeziret Faraún, mediæval *Graye*, a rocky islet with the ruins of a castle built by Baldwin I. (circ. 1115). The village of 'AKABAH was transferred from Egypt to Turkey in 1892, and has a small import trade. Near it was *Elath*, the port from which Solomon's fleet sailed to Ophir, which as *Ælana* was the station of the tenth Roman legion, and a place of commercial importance. As *Haila* or *Ailat*, under the Arabs, it was in the 10th century the great port of Palestine and the emporium of the Hejáz.

Akalkot, a native state of India, in the Deccan division of Bombay, ranking as one of the Satara Jagirs, situated between the British district of Sholapur and the Nizam's dominions. Area, 498 square miles; population

(1891), 75,744; (1901), 82,052, showing an increase of 8 per cent. In 1897-98 the gross revenue was Rs.3,52,867, of which Rs.39,102 was expended on public works; the tribute is Rs.14,592; the number of police was 59; there were 38 schools, with 1897 pupils. The chief, who is a Mahratta of the Bhonsle family, resides at Poona on a pension, while the state is under British management. The town of AKALKOT is situated in 17° 31' N. lat. and 76° 15' E. long., near the Great Indian Peninsula railway, which traverses the state. Population, 6551.

Akanyam, R. See NILE.

Akassa. See NIGERIA.

Akhal-teke. See TRANSCASPIAN TERRITORY.

Akhaltzykh (Georgian *Ahaltzykhé*, "new fortress"), a fortified district town of Russia, Transcaucasia, government of Tiflis, 67 miles east of Batum, situated on a tributary of the Kura, at an altitude of 3370 feet. It enjoys an excellent climate and its houses are scattered amidst gardens. The new town is on the right bank of the river, while the old town and the fortress are on the opposite bank. It has a considerable inland trade, and brown coal is found in the neighbourhood. In 1897 the population, of whom many were Armenians, was 15,387.

Ak-hissar, the classical *Thyateira*, the "town of *Thya*," situated in a fertile plain, on the Geurduk Chai (*Lycus*), in the Smyrna viláyet. *Thyateira* was an important station on the Roman road from Pergamos to Laodicea, and one of the "seven churches" of Asia (Rev. ii. 18). The town is connected with Smyrna by railway and exports cotton, wool, opium, cocoons, and cereals. Population, 13,000 (Moslems, 8200; Christians, 4800).

Akhtyrka, a district town of Russia, government of Kharkoff, near to the Vorskla river, connected by a branch (11 m.) with the railway from Vilno to Nikolaevsk. It is surrounded by moving sands, and often inundated. It has a beautiful cathedral, built upon a plan by Rastrelli in 1753, to which numerous pilgrims come every year to venerate the ikon of the Virgin of Akhtyrsk. There is an active trade in corn, cattle, and the produce of domestic industries. Population (1897), 23,390.

Akim. See GOLD COAST.

Akkerman (Turkish *Ak-herman*, "white town"), a district town, formerly a fortress, of South-West Russia, government of Bessarabia, situated on the right bank of the estuary of the Dnieper, 12 miles from the Black Sea. It was taken by the Russians in 1770 and 1774 and returned to the Turks, but was definitely annexed to Russia in 1881. Its proximity to Odessa gives it an advantageous position for trade, and it does a thriving business in wine, salt, fish, wool, tallow, &c. The town, with its three suburbs, contains beautiful gardens and vineyards. In 1897 the population was 28,303, or 40,000 including the suburbs.

Akmolinsk, in Asiatic Russia, the north-eastern of the three provinces belonging to the general governorship of the Steppes, formerly known as the Kirghiz Steppe; bounded by Turgai on the W., Tobolsk on the N., Tomsk on the E., and Russian Turkestan on the S. Area, 211,566 square miles, of which 4535 are lakes. It is low and dotted with salt lakes in its northern portion, and sandy on the banks of the Irtysh. An undulating plateau stretches in the middle, and is watered by the Ishim, the plains gradually rising southwards, where a wide spur of the Tarbagatai Mountains runs north-westwards, containing gold, copper, and coal. Many lakes, of which the largest is Denghiz, are scattered along the northern slope of these hills. To the south of these hills, towards Lake Balkhash,

situated on its south-eastern frontier, and to the north-west of this lake, spreads a wide waterless desert, Bek-pak-dala, or Famine Steppe (Golodnaya). The province is watered by the Ishim, tributary of the Irtysh (which flows near to the eastern frontier) and the Nura. The climate is very continental and dry, the average temperatures at Akmolly being: year 35°, January 1·5°, July 70°; yearly rainfall, only 9 inches. The population, which was 678,957 in 1897 (324,587 women) consists chiefly of Russians in the northern and middle portions, and Kirghiz (about 350,000), who breed large quantities of cattle, horses, and sheep. The urban population was only 74,069. Agriculture is successfully carried on in the north, where the Siberian railway runs from Zlatoust to Omsk through a very fertile, well-populated region. Steamers ply on the Irtysh. The province is divided into five districts, the chief towns of which are: Omsk, formerly capital of West Siberia (37,470 inhabitants); Akmolinsk, or Akmolly, chief town of the province (9560), situated on the Ishim, 285 miles south-west of Omsk, and chief centre for the caravans coming from Tashkent and Bukhara; Atbasar, 3030; Kokchetav, 5000; and Petropavlovsk, 20,014.

Akola, a town and district of India, in Berar or the Haidarabad Assigned Districts, under British administration. The town is on the Morna river, 930 feet above the sea; railway station, 363 miles from Bombay. Population (1881), 16,608; (1891), 21,470; municipal income (1897-98), Rs.45,057. It is a centre of trade in raw cotton. There are 13 factories for ginning and pressing cotton, with an out-turn of 80,000 bales. It has a high school, with 202 pupils in 1896-97; a training college, with 69 students; an industrial school, supported by a Christian mission; an engineering class; two printing presses, each issuing a vernacular newspaper.

The district of AKOLA has an area of 2660 square miles; population (1881), 592,792; (1891), 574,782, showing a decrease of 3 per cent; average density, 216 persons per square mile; (1901) 582,763, showing an increase of 1 per cent. Land revenue and rates in 1897-98 amounted to Rs.22,34,308, the incidence of assessment being R.1:7:2 per acre; the cultivated area was 1,303,757 acres, of which 9344 are irrigated from wells; number of police, 601 men; the number of boys at school in 1896-97 was 12,412, being 27·8 per cent. of the male population of school-going age; the registered death-rate in 1897 was 54·9 per thousand. The principal crops are millet and cotton.

Akron, a city of Ohio, U.S.A., the capital of Summit county, situated in 41° 05' N. lat. and 81° 32' W. long. in the north-eastern part of the state, at an altitude of 1000 feet, being on the divide between Lake Erie and Ohio river. The water supply is derived from wells. The plan of the streets is quite irregular; there are six wards, and the city is entered by no fewer than six railways, giving it excellent connexions in all directions. Its industries are chiefly manufacturing, and its products consist largely of agricultural implements, cement, brick, and tiles. Buchtel College, one of the smaller institutions of learning, is situated here. The population in 1880 was 16,512, in 1890 it was 27,601, and in 1900 it was 42,728.

Ak-Shehr, the classical *Philomelion*, a town in Asia Minor, in the Konia viláyet, situated at the edge of a fertile plain, on the north side of the Sultan Dagh. *Philomelion* was on the great Greco-Roman highway from Ephesus to the east, and to its townsmen the Smyrniotes wrote the letter that describes the martyrdom of Polycarp. The town is connected by railway with Konia, Smyrna, and Constantinople. Population, 15,000 (Moslems).

Aksu (*White Water*), a town of the Chinese empire, Eastern Turkestan, in 41° 7' N. and 79° 7' E., 70 miles E. of Uch-Turfan and 270 miles N.E. of Yarkand, near to the left bank of the Aksu river, which takes its origin in the Tian-shan Mountains and joins the Tarim. It belongs to the series of oases (Uch-Turfan, Bai, Koucha, &c.) situated at the southern foot of the eastern Tian-shan Mountains. The town, which is supposed to have about 6000 houses, is enclosed by a wall. It is an important centre for caravan routes, and has a considerable trade. Extensive cattle breeding is carried on by the inhabitants.

Aktyubinsk (AK-TUBE), a district town and fort of Russian Central Asia, province Turgai, situated on the Ilek river, 135 miles S.E. of Orenburg. It is the centre for the administration of the Kirghiz, with whom a lively trade is carried on. In 1897 the population was 2840.

Akyab, a district and city in the Arakan division of Burma, lies along the north-eastern shores of the Bay of Bengal. The district area is 5136 square miles. Population (1891), 415,305; (1901), 482,374. There were 2040 villages paying a revenue of Rs.16,91,191 in 1898-99. Buddhists and Jains numbered 258,259, Mahommedans 119,157, Hindus 9762, aborigines 28,234, and Christians (European and native) 893. Of the total area of 3,287,040 acres, the area under cultivation was 590,991, there were 64,950 acres lying fallow, the cultivable waste amounted to 1,669,478 acres, and 961,621 acres were not capable of cultivation. The rainfall in 1898-99 was 193.49 inches. AKYAB, the chief town, had in 1891 a population of 37,938; in 1871-72 the total was 15,281. It has a municipality with a committee of 16 members, 10 of whom are elected. There is a second-class district jail. The export of rice from Akyab has increased greatly of late years. There are two oil-wells in the district, both on Boronga island, worked under the Canadian oil-boring system. During the year 1898-99, 290 vessels with a tonnage of 167,168 entered the port, and 282 of a burden of 166,752 cleared.

Ala, a town in South Tyrol, Austria, in the government district of Rovereto, on the Adige river, at the entrance of the Ronchi valley. It is the last station on the Brenner railway, and has an Austrian and an Italian custom-house. Silk and velvet manufactures. Population in 1890, 4646; in 1900, 4933, chiefly Italian.

Alabama, one of the Southern States of the American Union, situated between 35° and 30° 13' N. lat., and 84° 53' and 88° 35' W. long., and bounded on the N. by Tennessee, on the E. by Georgia, on the S. by Florida and the Gulf of Mexico, and on the W. by Mississippi. In the last quarter of the 19th century Alabama experienced a new era of prosperity. During the decade of the Civil war the cotton product had fallen off from 989,955 bales in 1860 to 429,482 bales in 1870, and the corn product from 33,226,282 bushels to 16,977,948 bushels, these being the leading products of the State, which was almost entirely agricultural. Politically and economically the result of the war was even more marked. The emancipation and enfranchisement of the negroes, who constituted almost half of the population (475,510 coloured in a total of 996,992), threw the Government into the hands of strangers, "carpet-baggers," who were attracted mainly from the north by the prospect of political power. When these went into office under the constitution born of the bayonet, their auditor said in his first report: "Alabama stands in a proud position in the

financial world. . . . Nothing but gross mismanagement of her finances will cause her credit to decline."

The State's bonded debt was . . .	\$5,270,000.00
Educational fund and miscellaneous . . .	\$3,085,683.51
Total . . .	\$8,355,683.51

Under the new régime the State's endorsement was granted to railways to the extent of \$16,000 a mile; and many roads were begun, partially completed, and then abandoned. So gross was the mismanagement in general that, before the close of 1873, the governor was compelled to report to the legislature his inability "to sell for money any of the State bonds," a condition of things which, according to an official report (30th September 1874), had resulted from the fact that the debt had grown to the sum of \$25,503,593, including both direct and endorsed railway securities. At this crisis the white people, worn out by misgovernment at the hands of irresponsible rulers, resolved to re-establish the public affairs of the commonwealth upon a normal basis. Under the lead of George S. Houston, the bulk of the white voters united in the democratic and conservative party triumphed in the memorable contest of 1874, electing not only the governor, but large majorities in both branches of the legislature. The affairs of the State were again in the hands of the taxpayers. That event made possible the political, economic, and industrial reorganization which has since lifted the State to its present condition of prosperity, not only as an agricultural community, but as one of the great coal and iron-producing States of the Union.

Under the constitution of 1875, which superseded that of 1868, and which is still in force, official salaries and the power of the legislature to indulge in financial extravagance were severely restricted. The debt, then beyond the ability of the State to bear, was readjusted, and was so reduced by amicable settlements that, on 30th September 1888, it had shrunk from \$25,000,000 to \$12,085,220. Owing to subsequent payments, the total bonded debt amounted on 1st March 1898 to only \$9,357,600.

The total population, which had increased in 1890 to 1,513,017 (833,718 whites and 679,299 negroes), was 1,828,697 in 1900, showing an increase for the decade of 20.8 per cent. The total land surface of Alabama is, approximately, 51,540 square miles, and the density of population was therefore 35.4 per square mile in 1900, as compared with 29.3 ten years earlier. There were, in 1900, 201 incorporated cities, towns, and villages, and of these 9 had a population in excess of 5000, and 3 in excess of 25,000. These three were Mobile, with 38,469 inhabitants, Birmingham, with 38,415, and Montgomery, with 30,346. The proportion of rural to urban population is increasing. The total taxable values, which in 1876 were \$135,535,790, were in 1898 \$256,256,295, the total state tax being 5½ mills on the total values. The total cotton product, which in 1870 was 429,482 bales, was in 1899, 1,130,000 bales.

The main feature in the modern transformation is the vast development of the mineral region, which occupies the north-eastern two-fifths of the State. The south-eastern fourth of this area, the Gold Belt, produces gold, copper, pyrites, and mica. In the north-western three-fourths are the three coal-fields—Warrior, Cahaba, and Coosa—aggregating 8000 square miles (about 2000 productive), separated by narrow north-east and south-east valleys, in which are bauxite, barytes, iron ores, and limestones. Thus all the raw materials for the production of iron occur in close proximity, with no natural barriers between. The total annual coal production, which in 1870 amounted only to 13,200 tons, had risen in 1875 to 67,200; in 1880 to 380,000; in 1885 to 2,492,000; in

1890 to 4,090,409; in 1895 to 5,693,775; and in 1899 to 7,500,000 estimated. Prof. M'Calley has reached the conclusion that the three coal-fields (Warrior, Cahaba, and Coosa), combined, probably contain an aggregate of at least 42,100,000,000 tons. Tests made by the United States navy have established the superior quality of certain seams of this coal for steam purposes, while the coke tonnage of the Pratt and Blue Creek seams of the Warrior field (1,609,839 tons in 1898) is second only to the famous Connellsville district of Pennsylvania. The pig-iron production, which during the year 1870 amounted only to 7060 tons, had risen in 1875 to 22,418; in 1880 to 68,925; in 1885 to 203,069; in 1890 to 816,911; in 1895 to 854,667; and in 1899 to 1,083,905. The supply of iron ore (red and brown) is practically inexhaustible. That used in the Birmingham district is principally of the red fossiliferous kind derived from Red Mountain, the vein running about 20 feet thick at the outcrop, and extending under cover at an angle of from 15 to 20 degrees from the horizontal to an unknown depth. Birmingham, Ala., is now the third largest point of export of pig-iron in the world,—Middlesbrough in England being the first, and Glasgow in Scotland the second. Within the eighteen months ending 1st January 1898 there were exported from Birmingham 297,000 tons of pig-iron to all parts of the world. During the year 1899 the production of steel began in the Birmingham district, one plant producing 9670 tons and another 2263.

To render the waterways available for commerce, the Federal Government has spent millions of dollars. The Mobile river, with its branches, resembles a gigantic tree rising from tidal limits in one of the best harbours on the Gulf of Mexico, and spreading northward, eastward, and westward into Tennessee, Mississippi, and Georgia. The total of mileage of rivers in use to-day either for commercial purposes or in the process of improvement by the Federal Government, is 2214 miles. On either side the mineral region is pierced by the Warrior and Coosa rivers, destined soon to be the great highways through which the coal and iron products are to be brought in barges to tidal limits for shipment through the port of Mobile. The deepening of Mobile harbour in the south, the construction of the Muscle Shoals Canal on the Tennessee river in the north, and the improvement of the interior rivers have involved an expenditure upon the part of the Federal Government of about twelve millions of dollars, nearly all of which has been appropriated since 1870. The most important part of the work now in progress is the improvement of the Warrior river, the early completion of which has been assured by the action of Congress placing it under the contract system directed by the secretary of war. In order, however, to give an outlet for coal and iron by water from the heart of the best mineral region, it is necessary to cut a canal about 64 miles long from Birmingham to the Warrior, *vid* Bessemer. After a careful survey Major Russell, the Government engineer-in-charge, declared that "the project is both feasible and advisable." A waterway will thus be opened through which coal and iron, mined within 300 miles of tidal limits, can be floated to the sea. Experts estimate that a ton of pig-iron can be loaded at Birmingham and landed at Mobile at 49 cents, a rate 55 cents lower than any yet in existence. The cost of steam coal at Mobile is now about \$2.80 a long ton, the cost of railway transportation being about \$1.25. After the canal and Warrior route has been made available, a scrupulous estimate places the cost of such coal at Mobile at \$1.50. The railway system of the State has also been steadily developing. The 1602 miles of railway in operation in 1871 had increased to 3560 miles at the close of 1898.

Mobile is the only seaport of the State. The bay is about 32 miles long, with an average width of 16 miles. The United States Government has dredged a channel, now 23 feet deep, from the docks to deep water. At the mouth of the bay there is a deep water cup, with a depth of from 30 to 60 feet, and an area of 5 or 6 square miles. The bar separating this deep water from the water of the gulf has a depth of 23-1/2 feet, which has been increasing by natural processes since the earliest Government records. Estimates by Government engineers have settled the fact that a channel across this bar can be cut to a depth of 30 feet, with a width of 300 feet, by the excavation of 220,000 cubic yards of material at a cost insignificant when compared with the value of the improvement. If that work is completed, Mobile Bay may be entered at any time by vessels drawing 28 feet—something that can be said of few land-locked harbours.

During the year ending 30th June 1870, 105 vessels of 70,249 tons entered, and 129 vessels of 81,276 tons cleared, in the foreign trade. During the year ending 30th June 1900, 755 vessels of 549,198 tons entered, and 717 vessels of 505,273 tons cleared. For the year ending 30th June 1901 the total imports were \$3,008,449, and the total exports, \$11,837,105. The thirteen mills manufacturing cotton goods in 1870 have been increased to fifty-two, with 813,939 spindles and 18,590 looms, the total capital invested amounting to \$16,278,780. The annual output of the cotton oil mills of the State is 139,500 tons, valued at \$2,929,500. The lumber and shingle mills, numbering about 1000, represent an invested capital of \$18,700,000, the average output per day for each mill being 15,000 feet. The annual product of rosin and naval stores is valued at \$1,150,000.

The number of national banks in operation, 31st October 1900, was 30, with paid-up capital of \$3,555,000, and outstanding circulation of \$1,968,665. The state banks numbered in the same year 62, with a capital and surplus of \$3,292,874; the private banks 26, with a capital and surplus of \$1,021,078; and the loan and trust companies 9, with capital and surplus of \$869,723.

In 1890 Alabama had 6013 church edifices, and church property valued at \$6,768,477. There were 559,171 communicants or members, of whom 258,405 were Baptists, 242,624 Methodists, 21,502 Presbyterian, and 13,230 Roman Catholics.

The law establishing a public school system was enacted in 1854, but it was twenty years after that date before the period of substantial, permanent growth began. The school term ranges from four to nine months, and tuition is free. Separate schools are provided for children of African descent. The funds for maintaining the public schools are derived from a direct appropriation from the state treasury, a special state school tax, a poll tax, interest on the sixteenth section fund, and municipal appropriations. In 1855 they amounted to \$237,515.39. In 1900 the appropriations for common school education amounted to \$1,100,000.00. The school age is from seven to twenty-one years. In 1855 the enumeration showed a white school population of 145,588. In 1899 the number was 633,546—white, 350,667; coloured, 282,879. The State is thoroughly committed to the policy of universal education at governmental expense, and is making rapid progress in that direction. Besides the public schools, Alabama has a number of private and denominational institutions of learning of high grade. All the leading denominations are well represented in this number. The amount expended on private and denominational education annually approximates \$300,000.

The special question with which Alabama, in common with her

sister Southern States, is confronted, is the race problem. The constitution of 1875, under which the political supremacy of the white race was re-established, provides (Art. XIII. sec. 1) that a system of public schools shall be maintained throughout the State "for the equal benefit of the children thereof . . . but separate schools shall be provided for the children of citizens of African descent." From that time negro children have been enjoying in their separate schools the equal benefits of an educational fund of approximately one million dollars a year, the bulk of which is produced by taxes contributed by the whites. In spite of this, however, the great mass of negroes, in whose hands rests so large a proportion of the political power, have little or no training in the duties of citizenship. In the hope of solving the race problem upon a broad and humane basis a South Conference was formed in Alabama, the first meeting of which was held under brilliant auspices. The chief difficulty is, of course, that of franchise. If it is to be limited by educational or property qualifications, whatever disabilities may be imposed must rest upon both races alike. If the negro shall be disfranchised by his illiteracy, he can remove the disability in the schools which the white people of the State maintain for his equal benefit. Such a plan, if adopted as in other Southern States, will result in a gradual and conservative political emancipation.

Alabama Arbitration. See ARBITRATION, INTERNATIONAL.

Alagoas, an Atlantic state of Brazil. Its area covers 22,580 square miles. The population in 1872 was 348,009, and in 1890, 511,440. The capital is Alagoas Maceió, and amongst other towns are Camaragibe, Penedo, S. Miguel dos Campos, Pilar, and Porto Calvo. The state has railways from Maceió to Muricy and Viçosa, and from Piranhas to the Rio Moxotó. ALAGOAS MACEÍO, with a population of 30,000, is an important shipping port, visited by Transatlantic steamers, and the terminus of the Alagoas railway (55 miles).

Alais, chief town of arrondissement, department of Gard, France, 27 miles N.W. by N. of Nîmes, on railway from Paris to Nîmes, *viâ* the Cevennes. Amongst the public institutions are the municipal chemical laboratory and two hospitals. Sericulture is extensively engaged in, and silk, both raw and manufactured, furnishes a large part of the town's widespread trade. Pasteur here prosecuted his early investigations. A statue has been erected to his memory. The chemist Dumas was a native of Alais. Population (1881), 16,945; (1891), 18,333; (1896), 18,249.

Alajuela, a province of Costa Rica, Central America. Its area is 4250 square miles, and the population in 1897 numbered 60,000. The capital is Alajuela, and amongst other considerable towns are San Ramón, Grecia, Atenas, and Naranjo. The province is divided into seven cantons.

Alajuela, capital of the above province, situated at the terminus of the railway line from Limón, 12 miles W. of San José, and 23 miles W.N.W. of Cartago. It has some trade with Punta Arenas, 23 miles distant by mule road, and on the formation of the new port on the Pacific at the head of the Gulf of Nicoya will increase in importance. Population, 7000.

Alameda, a residential city of Alameda county, California, U.S.A., is situated in 37° 46' N. lat. and 122° 16' W. long., on the east side of San Francisco Bay, directly south of Oakland, and separated from it by San Antonio creek. Its site is low and level and its plan fairly regular. It is entered by the Southern Pacific railway. The population in 1880 was 5708, in 1890 it was 11,165, and in 1900 it was 16,464.

Alantika, Mount. See CAMEROON.

Alarcon, Pedro Antonio de (1833-1891), Spanish writer, was born on 10th March 1833 at Guadix. He graduated at the university of Granada, studied law and theology privately, and made his first appearance as a dramatist before he was of age. Deciding to follow lit-

erature as a profession, he joined with Torcuato Tárrego y Mateos in editing a Cadiz newspaper entitled *El Eco de Occidente*. In 1853 he travelled to Madrid in the hope of finding a publisher for his long continuation of Espronceda's celebrated poem, *El Diablo Mundo*. Disappointed in his object, and finding no opening at the capital, he settled at Granada, became a Radical journalist in that city, and showed so much ability that, in 1854, he was appointed editor of a very advanced journal, *El Látigo*, published at Madrid. The extreme violence of his polemic writings led to a duel between him and the Byronic poet, José Heriberto García Quevedo. The earliest of his novels, *El Final de Norma*, was published in 1855, and though its construction is feeble, it brought the writer into notice as a master of elegant prose. A small anthology, called *Mañanas de Abril y Mayo* (1856), proves that Alarcón was recognized as a leader by young men of promise, for among the contributors were Castellar, Manuel del Palacio, and López de Ayala. A dramatic piece, *El Hijo prodigo*, was hissed off the stage in 1857, and the failure so stung Alarcón that he enlisted under O'Donnell's command as a volunteer for the war in Morocco. His *Diario de un testigo de la guerra de Africa* (1859) is a brilliant account of the events of the expedition. The first edition, amounting to fifty thousand copies, was sold within a fortnight, and Alarcón's name became famous throughout the Peninsula. The book is not in any sense a formal history; it is precisely what its title implies, a series of picturesque impressions told with remarkable force. On his return from Africa Alarcón did the Liberal party much good service as editor of *La Política*, but his marriage to a devout lady, Paulina Contrera y Reyes, in 1866, led him to modify his political views considerably. On the overthrow of the monarchy in 1868, Alarcón advocated the claims of the Duc de Montpensier, was extremely neutral during the period of the Republic, and declared himself a Conservative upon the restoration of the dynasty in December 1874. These political variations alienated Alarcón's old allies and failed to conciliate the royalists. But though his political influence was ruined, his success as a writer was greater than ever. The publication in the *Revista Europea* (1874) of a short story, "El Sombrero de tres picos," a most ingenious resetting of an old popular tale, made him almost as well known out of Spain as in it. This remarkable triumph in the picaresque vein encouraged him to produce other works of the same kind; yet, though his *Cuentos amatorios* (1881), his *Historietas nacionales* (1881), and his *Narraciones inverosímiles* (1882) are pleasing, they have not the delightful gaiety and charm of their predecessor. In a longer novel, *El Escándalo* (1875), Alarcón had appeared as a partisan of the neo-Catholic reaction, and this change of opinion brought upon him many attacks, mostly unjust. His usual bad fortune followed him, for while the Radicals denounced him as an apostate, the neo-Catholics professed that *El Escándalo* was tainted with Jansenism. Of his later volumes, written in failing health and spirits, it is only necessary to mention the *Capitán Veneno* and the *Historia de mis libros*, both issued in 1881. Alarcón was elected a member of the Spanish Academy in 1875. He died at Madrid, after a long and painful illness, on the 20th of July 1891. The impression which he makes upon the reader is brilliant, but unenduring. His later novels and tales are disfigured by their didactic tendency, their feeble drawing of character, and even by certain Gallicisms of style. But, at his best, Alarcón may be read with great pleasure. The *Diario de un testigo* is still unsurpassed as a picture of campaigning life, while "El Sombrero de tres picos" is a very perfect example of malicious wit and minute observation. (J. F. K.)

Alard, Jean Delphin (1815-1888), a distinguished French violinist and teacher, was born at Bayonne, 8th May 1815, and died at Paris, 22nd February 1888. He was a pupil of the Paris Conservatoire, under Habeneck, from 1827; he succeeded Baillot as professor there in 1843, and retained the post till 1875. His playing was full of fire and point, and his compositions, consisting mainly of fantasias and such things, had a great success in France, while his *Violin School* had a wider vogue and considerably greater value.

Ala-shehr, the classical *Philadelphia*, a town of Asia Minor, in the Smyrna vilayet, situated in the valley of the Kuzu Chai (*Cogamus*), at the foot of Boz Dagh (*M. Imolus*). Philadelphia was a Pergamene foundation, was one of the "seven churches" of Asia, and was called "Little Athens" on account of its festivals and temples. It was an independent, neutral city when taken in 1390 by Sultan Bayazid I., and an auxiliary Christian force under the Emperor Manuel II. The town is connected by railway with Konia and Smyrna. There are small industries and a fair trade. From one of the mineral springs comes a water known in commerce as "Eau de Vals." Population, 22,000 (Moslems, 17,000; Christians, 5000).

Alaska.—Alaska, formerly RUSSIAN AMERICA, is a territorial district of the United States, occupying the north-western extreme of North America and adjacent islands. The inhabitants of the Aleutian islands called the continental land eastward from them Alayeksha, which was corrupted by early Russian explorers to Aliashka. The name was subsequently restricted to the peninsula, and, in the simplified form now adopted, was proposed as a name for the new territory by Charles Sumner in a speech before the U.S. Senate advocating its purchase. The territory of Alaska comprises, first, all that part of continental North America west of the 141st meridian from Greenwich; secondly, the eastern Diomed Island in Bering Strait and the islands of Bering Sea, and the Aleutian chain east of a line drawn from the Diomedes in a south-westerly direction so as to pass midway between Attu Island of the Aleutian, and Copper Island of the Commander group; lastly, of a narrow strip of coast with its adjacent islands, north of lat. 54° 40' N., west of Portland Channel, and thence, as designated in the treaty of cession, bounded to the east and north by a line, following "the summit of the mountains situated parallel to the coast" "to the point of intersection with the 141st meridian," provided that when this line "shall prove to be at a distance of more than ten marine leagues from the ocean the limit" "shall be formed by a line parallel to the windings of the coast and which shall never exceed the distance of

SKETCH MAP OF THE ALEUTIAN ISLANDS.

ten marine leagues therefrom." The islands comprise several main groups: the Alexander Archipelago, extending from the southern boundary north-westward to Cape Spencer; the Kadiak group, south-east of the peninsula of Alaska; the Catherina Archipelago, westward from the end of the peninsula to Attu, and is further subdivided into four minor groups—the Fox, Andreanoff, Rat, and Nearer Islands, often collectively designated the Aleutian Islands. Northward from the Aleutian group, in Bering Sea, are the Pribiloff or Fur Seal Islands, St. Matthew,

and St. Lawrence, at subequal distances, and the large island of Nunivak eastward near the coast. The estimated area of the Alexander Archipelago is 31,205 square miles, and of the Aleutians 6391 square miles. The total area of the territory is approximately 580,107 square miles. From north to south it extends about 1200 miles, and from east to west nearly 2400 miles.

The coast-line, omitting minor sinuosities but including the islands, exceeds 16,000 miles. Beginning at the south and proceeding northward and westward the most conspicuous capes are Muzon, Ommaney, Spencer, St. Elias, Newenham, Vancouver, Romanzoff, Prince of Wales (the westernmost point of the continent), Lisburne, Icy Cape, and Point Barrow, the last being the most northern point of the territory and situated in lat. 71° 21' N. and long. 156° 15' W. Three great peninsulas project from the shores: Kenai, to the east of Cook's Inlet, the peninsula of Alaska, and the Kaviak peninsula between Kotzebue and Norton Sounds. The great embayment north of a line drawn from Queen Charlotte Islands to Kadiak has been named the Gulf of Alaska. Omitting the interstices of the archipelago, Yakutat Bay, Prince William Sound, Cook's Inlet, are the principal arms of the gulf. The eastern shores of Bering Sea are indented by Bristol Bay, north of the Alaska peninsula, and Norton Sound, south of the Kaviak peninsula; north of the latter Kotzebue Sound is the only inlet of importance.

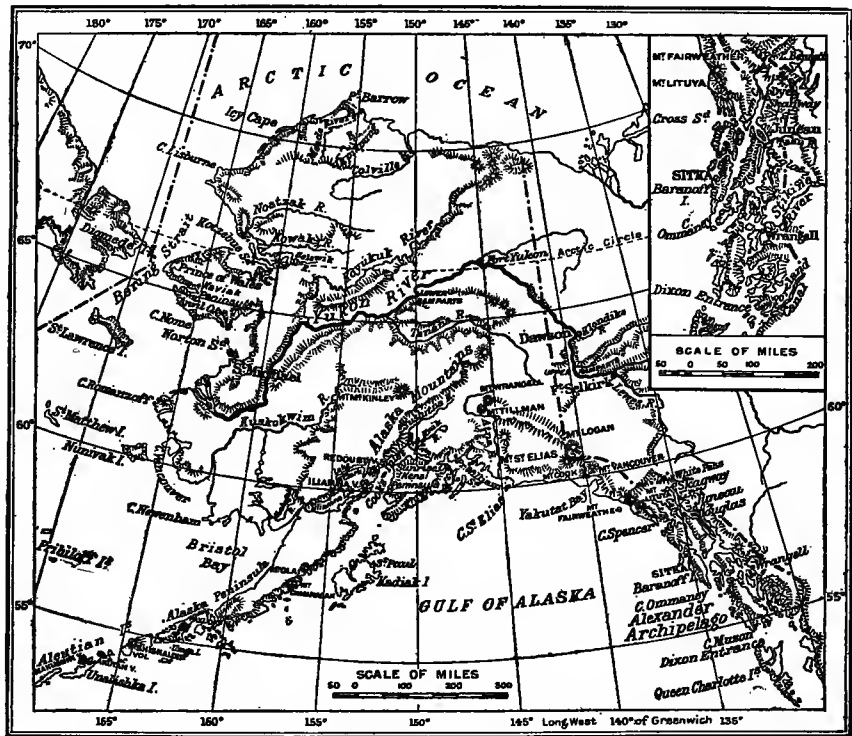

The entire north-west coast of America is folded by mountain-building forces in general harmony with the trend of the coast. The state of Washington, British Columbia, and south-eastern Alaska have had their strata violently and sharply crumpled, the lines of elevation and depression being roughly N.N.W. and S.S.E., with occasional transverse depressions. These have been the site of a vast system of glacial action which has deepened and modelled the valleys, though its processes were never carried far enough to cut down and remove the intervening ridges. The result is what has been aptly termed a "sea of mountains," in which the existing glaciers, stupendous as many of them are, are mere tatters of the ice that preceded them. Consequently this coast, unlike that of Norway, which in outline is not dissimilar, is bold, steep, and craggy, with few beaches and hardly level shore enough anywhere to build a cabin on or cultivate a garden patch. Nevertheless the mountain sides are densely wooded with evergreens, the snow-line being at an approximate elevation of 3000 to 5000 feet, according to location. The passages of the archipelago are merely submerged portions of this broken area, and would be reduplicated to the eastward were the level of the land to be still further depressed. The summits are of unusually even elevation, and, near the sea, present no peaks of remarkable height. North-westward from Cape Spencer the mountain-building forces seem to have been more intense and the ranges of the Fairweather and St. Elias Alps rise to great heights at a short distance from the sea. Mt. Fairweather (15,300 feet), Lituya (12,000), Laperouse (10,750), Cook, Vancouver, St. Elias (18,100), and, further inland, Logan (19,500), are the most noteworthy summits of this region. The Muir glacier, the Malaspina, and the Bering glacier flank portions of these mountains and rank next to those of Greenland. These mountains continue westward parallel with the coast and terminate as the backbone of the Kenai peninsula. Parallel uplifts further inland near the meridian of 145° W. rise to great heights. Mt. Tillman has been assigned a height of 16,600 and Mt. Wrangell of 17,500; the latter, on somewhat insufficient evidence, has been ranked as a volcano. Still further north and west a range which corresponds in general with the line of the range of the Alaska peninsula further

south and west, and which has been named the Alaskan mountains, culminates in lat. 64° N. in the peak of Mt McKinley, rising over 20,000 feet. Beyond the Alaskan range and its foothills lie broad river valleys, north-westward from which are ranges of comparatively low hills, none of which have been recorded as exceeding 3500 feet, and beyond which again stretches the Arctic tundra.

Much of the rock of North-Western Alaska is volcanic. Along the great line of orographic folding indicated by the Alaskan range and the Aleutian chain numerous remarkable volcanic peaks exist, varying in height up to 12,000 feet. Enumerating them from Cook's Inlet westward, and omitting all cases of doubtful vulcanicity, the most notable are Redoubt Volcano, Iliamna, Augustin, Olai, Chiginagak, Pavloff, Isanotski (extinct), Shishaldin, Akutan, Makushin, Vsevidoff, Atka, Gareloi, and Semisopochnoi, all of which, with the exception noted, emit steam or smoke, or show other evidences of activity. North of the Alaskan range no active volcanoes are at present known.

The transverse depressions of the mountainous continental border are occupied by rivers and continued as straits. Thus the Naas river, just south of the boundary, corresponds to the trough of Dixon Entrance and Portland Channel, the Stikine to that of Sumner Strait, the Taku to that of Cross Sound. The summit of the mountains at the head of Lynn Canal, situated about 15 miles from the sea, has an elevation of 2800 feet (White Pass) to 3500 feet (Chilkoot Pass); and here only, on the whole extent of the South-Eastern Alaskan coast, is a clear-cut watershed exhibited between the seaboard and interior drainage. Between the Alexander Archipelago and the peninsula of Alaska but few rivers make their way across the ranges to the sea, chiefly through difficult canyons. The Atna, or Copper river, is the most important of these and reaches the sea just east of Prince William Sound. At the head of Cook's Inlet a considerable valley is drained by the Knik (Fire) and Sushitna rivers. The latter rises in the Alaskan range. North-westward from the main axis of this range, especially towards the coast of Bering Sea, a number of large lakes exist, giving rise to rivers of some magnitude. West of Cook's Inlet, over the range, Lake Clark and Lake Iliamna feed the Kvichak river. Another assemblage of many smaller lakes is drained by the Nushagak river. Both empty into Bristol Bay. North of Cape Newenham Bering Sea receives the Kuskokwim, as yet hardly explored, but believed to have a length of 450 miles, chiefly through a rather mountainous country. Next northward in latitude about 62° 30', is the enormous delta of the Yukon, the chief river of Alaska and one of the great rivers of the world. It rises in British Columbia; the head of the branch called the Lewes river rising within 30 miles of the coast of Lynn Canal. Flowing in a north-westerly direction it cuts the Alaskan range, forming a canyon called the Upper Ramparts; a little later it receives the famous

Klondike river from the north-east, and enters Alaska in about lat. 65° N. Just above the Arctic circle, near the site of old Fort Yukon, it turns to the south-west, passes through the canyon of the Lower Ramparts, receives from the south-east a large tributary, the Tananá; 175 miles farther down receives the Koyúkuk river from the northward, bends more to the southward, and in about lat. 62° N. turns again to the north-west and debouches through a vast delta into Bering Sea, south of Norton Sound. The total length of the unsurveyed Yukon has been estimated at 2000 miles; near the delta, in spring, one bank is not always visible from the other. It is navigable for steamers of light draft nearly to its headwaters, navigation opening early in June and closing in October. In the summer of 1899 thirty-five steamers were in active service on its waters. North of Bering Strait a number of rivers fall into the Arctic Sea: of these the most notable are the Selawik, Kowak, and Noatak of

SKETCH MAP OF ALASKA.

Kotzebue Sound; the Meade, Ikpikpung, and Colville of the Arctic coast.

The region now known as Alaska was first explored by the Russian officers Bering and Chirikoff in 1741. They visited parts of the coast between Dixon Entrance and Cape St Elias, and returned along the line of the Aleutians. Their expedition was followed by many private vessels manned by traders and trappers. Spanish expeditions in 1773 and 1775 visited the south-eastern coast and laid a foundation for subsequent territorial claims. Cook in 1778 made surveys from which the first approximately accurate chart of the coast was published; but it was reserved for Vancouver, in 1793-94, to make the first charts, in the modern sense, of the intricate south-eastern coast, which only in recent years have been superseded by new surveys. Owing to excesses committed by private traders and companies, the trade and regulation of the Russian possessions was in 1799

History.

confided to a semi-official corporation called the Russian-American Company for a term of twenty years, afterward twice renewed for a similar period. Alexander Baránoff, one of the early administrators, became famous through the successes he achieved as governor. He founded Sitka, the present capital, in 1804, after the massacre by the natives of an earlier settlement at an adjacent point. In 1821 Russia attempted by ukase to exclude navigators from Bering Sea and the Pacific Coast of her possessions, which led to immediate protests from the United States and Great Britain. This led to a treaty with the United States in 1824 and one with Great Britain in 1825, by which the excessive demands of Russia were relinquished and the boundaries of the Russian possessions were fixed as at present. The last charter of the Russian-American Company expired 31st December 1861, and Prince Maksútóff, an imperial governor, was appointed to administer the affairs of the territory. In 1864 authority was granted to an American company to make explorations for a proposed Russo-American telegraph line overland from the Amur river in Siberia to Bering Strait, and through Alaska to British Columbia. Work was begun on this scheme in 1865 and continued for nearly three years, when the success of the Atlantic cable rendered the building of the line unnecessary and it was given up, but not until important explorations, especially of the Yukon region, had been made by Kennicott, Ketchum, Kennan, and Dall.

In 1867 negotiations with the Russian Government resulted in the purchase of Russian America by the United States for the sum of \$7,200,000, and on 18th October 1867 the formal transfer of the territory was made in Sitka. In 1870 the fur seal industry of the Pribiloff Islands was leased for twenty years to the Alaska Commercial Company under certain restrictions, producing for that period an average revenue to the Government of \$317,000. After the expiration of the lease in 1890 a renewal of the monopoly was secured by the North American Commercial Company at an increased rental. Pelagic sealing, which began to be of importance about 1882, made great inroads on the herds during their migrations; and it was contended that, owing to the killing of female seals in the waters of Bering Sea during the breeding season, the total destruction of this commercially valuable industry was imminent. After protracted negotiations between the United States and Great Britain the subject was referred to arbitrators, who met at Paris in 1893 and decided that the seals were *feræ naturæ*, but, in view of the interests involved, formulated regulations in the belief that they would mitigate the evils complained of.

In 1895 the discovery of rich deposits of gold on the Klondike tributary of the Yukon induced a vast immigration of prospectors, not only into British territory but into every part of Alaska, with the usual concomitants of hardship to those involved. Over 50,000 people are believed to have been engaged in this search for the precious metal, and a vigorous exploration of the territory by the United States Government was one of the results. Numerous placers were discovered in the gold belt, which extends in a general line from old Fort Selkirk on the Yukon to Bering Strait, with an average width of about 100 miles. The gold-bearing gravels are chiefly on the smaller tributaries of the Yukon, where numerous mining camps have sprung up with a fluctuating population. In 1898 gold was discovered on the north shore of Norton Sound at Cape Nome, and a year later the settlement of Anvil City in this district was reported to contain a population of 5000, and to have produced during 1899 nearly two millions of dollars.

Alaska may be divided climatologically and topographi-

cally into several districts. The *Sitka district* takes its shore water mainly from the Japanese current or Kuro Siwo, which performs for the Pacific such a function as does the Gulf Stream for the Atlantic; but owing to the much greater breadth of the Pacific, the heat and energy of the Kuro Siwo are greatly depleted before it reaches America. It crosses the ocean far south of the Aleutian Islands in about lat. 45° N. and impinges on the American coast near Queen Charlotte Islands. Thence one portion turns southward and the other northward and westward along the coast, becoming finally dissipated among the Fox Islands. To the warmth and moisture brought by this means the Sitkan district owes its fog and rain (80 to 103 inches per annum), its high mean temperature (43°·28), and its dense vegetation, chiefly of spruce, hemlock, and cedar. The narrow, deep channels, precipitous wooded slopes, multitudinous islands, and mainland glaciers make this district remarkably picturesque and characteristic, attracting thousands of tourists. It is inhabited by Indians of the Haida and Tlinkit stocks, who live chiefly by fishing and hunting. The principal settlements are Sitka on Baránoff Island, the capital of Alaska, where the chief officials are stationed; Douglas, on Douglas Island, a town grown up about the mines of the Treadwell lode, an enormous mass of low grade ore, reduced by mills of 800 stamps and producing nearly \$1,000,000 per annum; Juneau, on the mainland opposite, another mining town fed by the precious metals of the Silver Bow basin adjacent; and Skagway, at the head of Lynn Canal, the port of entry for the Yukon, which is reached by the Yukon and White Pass Railway from Skagway to Lake Bennett, in Canadian territory. A missionary colony on Annette Island, under the direction of the Rev. Mr Duncan, contains about 900 Indians of the Tsimpsyan stock from British Columbia, and is famous for its thrift and successful influence upon these people. Agriculture is difficult in this district, but potatoes and many garden vegetables are successfully grown. The *Kadiak district* includes Cook's Inlet, the peninsula of Alaska, and the Kadiak islands. It is less densely wooded, with more sunshine, less rain, and greater seasonal extremes of temperature. There is more arable land and the possibilities of agriculture are greater, but the mining resources apparently less. The district exists by its salmon fisheries, the waning fur trade, a few placer and quartz mines, and a little agriculture. There are large deposits of tolerably good Eocene lignite. The principal settlements are Sunrise City, a placer mining camp at the head of Turnagain arm of Cook's Inlet; St Paul, on Kadiak Island; and Unga, on the island of the same name, largely supported by the Apollo Mine, the second best quartz mine in Alaska, producing over \$200,000 in gold annually. The *Aleutian district* derives its name from traditions of islands beyond the Oliutorsk Cape of Kamchatka, which related to the Diomedes. When the Russians explored Bering Sea and found the Catherina Archipelago they transferred to it and its people the name of the long-sought Oliutorski Islands. The islands are destitute of trees but covered by a luxuriant growth of herbage, and have a foggy, somewhat boisterous, but less rainy climate than that of Sitka, with about the same mean temperature, very free from extremes. They are inhabited by the Unúngun (long known as Aleuts), a rapidly-decreasing race, half civilized, with many virtues and the usual aboriginal weaknesses. Their chief resource, the sea otter, is nearly exterminated, the fur seal industry in a state of decline, and the people live chiefly by fishing. There are no native land animals larger than the blue fox; but sea fowl are remarkably abundant, cod and other sea fish plentiful, and salmon obtainable in moderate quantity.

Agriculture is hardly practised, though a few vegetables are raised. The raising of sheep and reindeer is believed to be practicable on the less mountainous islands. The chief settlements are on Unaláshka Island, where Dutch Harbour is the principal port for Bering Sea commerce; Atka, on the island of the same name; and the small settlement of Attu, at the western extreme of the chain. The *Yukon district*, which may be taken as the vast region north-westward from the Alaskan mountains, has a colder and drier climate than those above mentioned, passing northward into Arctic conditions. The immediate shores are treeless, but the interior is fairly well wooded with spruce, poplar, and birch along the water-courses. The inhabitants of the coasts are Eskimo, of the interior Tinneh, or Athabaskan Indians. The search for gold has brought into the valley of the Yukon and its tributaries a large population of prospectors. The residents depend for substance chiefly upon salmon and white fish, with which the rivers swarm; wild fowl, which are very abundant; and the continental mammals, chief of which is the wild caribou. Mining for placer gold is the only industry, the fur trade being now unimportant, and there are few salmon canneries. The chief port for the Yukon is St Michael, on Norton Sound, though a large mining camp, called Anvil City, has been established at Cape Nome, on the north shore of the sound.

Though forming what is called a judicial and customs district, Alaska is still an unorganized territory, with a governor and some other officials appointed by the president. Since 1884 the people have vigorously worked for the extension of law and the organization of some kind of official system throughout the territory. Until recently these efforts have been but partially successful, but in 1900 a code for the administration of the territory under improved conditions became law. The total population in 1890 was 32,052, of whom 23,531 were natives, 1823 of mixed blood, and 4298 white. Of the natives 6000 were of Haida, Tsimpsonian, and Tlinkit stock; 3400 of the Tinneh tribes, 1000 Aleuts, and 13,100 Eskimo. The annual diminution of the native population (1880-90) was about 2 per cent., and of late the rate is believed to be much more rapid. It is estimated that the white population was in 1900 about 32,000.

The products of the territory have fluctuated with the decline of certain industries and the rise of others. In 1890 they were as follows:—

Fur seal	yearly average	value	\$1,744,200
Other fur	for ten years	"	628,400
Salmon (cases tinned, 642,175)	"	"	2,568,700
" (salted, 18,039 barrels)	"	"	162,351
Cod (salted, 760 tons)	"	"	38,000
Whale oil (12,503 barrels)	"	"	116,250
Whalebone (231,981 lb)	"	"	463,962
Walrus ivory (5799 lb)	"	"	3,000
Gold	"	"	4,604,500
Silver	"	"	27,340

The value of gold produced by the territory in 1899 is calculated by the director of the United States Mint to be \$4,610,000, and of silver \$258,585. The fur seal skins taken in 1887 on the Pribiloff Islands numbered 106,000; those taken by the pelagic sealers, 20,628. In 1897 the Pribiloffs could furnish only 19,200, while the pelagic catch was 24,321. The continental fur trade is waning, and, owing to competition, less profitable than formerly. The whale fishery, now carried on only for the baleen, as there is no profit on the oil, is reduced to eight vessels. The salmon and cod fisheries are reasonably prosperous. Mining has taken a great stride in advance, especially for the precious metals, and the prospect of valuable copper mines in the Prince William Sound region is believed to be good.

(W. H. D.)

Ala-tau (*Variegated Mountains*) is the name of three different mountain ranges in the Russian dominions in Asia: (1) the Kuznetsk Ala-tau is on the frontiers of Tomsk and Yeniseisk (*q.v.*); (2) the Dzungarian Ala-tau is in the province of Semiryechensk (*q.v.*); and (3) the Trans-Ili Ala-tau is in Turkestan (*q.v.*).

Alatyr, a district town of Russia, in the government and 107 miles N.W. of Simbirsk, on the Sura, a tributary of the Volga, in steamer communication with Vasilsursk on the Volga, and by rail with Kazañ (153 miles). It does considerable trade in corn and has some historically important monasteries. Population (1897), 11,090. The important river port of Promzino Gorodische (4350) is in its district.

Alava, a province in the north of Spain—one of the Spanish Basque Provinces, *q.v.*—with an area of 1200 square miles. The countship of Trevino (190 square miles), in the centre of the province, belongs to the province of Burgos. Population (1897), 94,642. There are two administrative districts and eighty-five parishes. Few provinces in Spain are inhabited by so laborious, active, and well-to-do a population. The primary schools are numerously attended, and there are very good normal schools for teachers of both sexes, and a model agricultural farm. The public roads and other works of the province are excellent, and, like those of the rest of the Basque provinces, entirely kept up by local initiative and taxes. Railways from Madrid to the French frontier, and from Castejon to Bilbao, both cross this province. The climate is mild in summer, fitful in autumn and spring, and very cold in winter, as even the plains are a high plateau surrounded on three sides by mountains always snowclad during several months. Asphaltic stone is quarried, and there are mineral waters at many places. The local industries are of some importance since 1880—foundries, manufactures of beds, furniture, railway carriages, matches, paper, sweets, woollen and cotton goods. Breadstuffs, colonial products, machinery are largely imported. The live stock in the province includes 7552 horses, 2844 mules, 1447 donkeys, 22,716 cattle, 68,066 sheep, 14,614 goats, and 21,355 pigs. Wheat is grown on 49,955 acres; oats, barley, rye, and maize on 28,075; vines on 36,000; and olives on 1795. Only four mines are actually worked; lead, blende, and lignite are produced.

Albacete, a province in the S.E. of Spain, with an area of 5971 square miles. Population (1897), 233,005. It is divided into eight districts and eighty-three parishes. The state and provincial roads are not in very good condition, and the municipal ones are worse. The climate is temperate in the mountainous parts of the Jurre Alcaraz district and in lower regions, but it is cold for months in the ranges that have peaks several thousand feet high; the rich and fertile valleys and some plains are most thickly peopled. The live stock in the province includes 1987 horses, 16,461 mules, 15,252 donkeys, 2410 cattle, 187,853 sheep, 50,687 goats, 22,113 pigs. Wheat

is grown on 342,415 acres, other cereals on 249,500 acres, vines on 98,630, and olives on 26,738. Two salt-mines are worked, and there are important lagoons.

Albacete, the capital of the above province, has a station on the Madrid-Alicante line. Modern erections

are, besides other buildings, the town hall, courts of justice, barracks, and provincial council palace. There are an institute, schools for teachers of both sexes, seven municipal and fifteen private schools. Matches are included in the manufactures. The population was 18,589 in 1887, and 21,637 in 1897.

ALBANIA.

ALBANIA, a portion of the Turkish Empire extending along the western littoral of the Balkan peninsula from the southern frontier of Montenegro to the northern confines of Greece, is perhaps the least known region in Europe; and though more than a hundred years have passed since Gibbon described it as "a country within sight of Italy, which is less known than the interior of America," but little progress has yet been made towards a scientific knowledge of this interesting land and its inhabitants. The wild and inaccessible character of the country, the fierce and lawless disposition of the people, the difficulties presented by their language and their complex social institutions, and the inability of the Turkish authorities to afford a safe conduct in the remoter districts, combine to render Albania almost a *terra incognita* to the foreign traveller, and many of its geographical problems still remain unsolved. The region of the Mirdites, the Mat district, the neighbourhood of Dibra, and other localities have never been thoroughly explored. The northern boundary of Albania has undergone some alteration in consequence of the enlargement of Montenegro, sanctioned by the Berlin Treaty (13th July 1878); owing to subsequent arrangements providing for the cession of Dulcigno to Montenegro (25th November 1880) in exchange for the districts of Plava and Gusinye, restored to Turkey, the frontier-line (finally settled December 1884) now ascends the Boyana from its mouth to Lake Sass, thence passes northward, and crossing Lake Scutari separates the district of Kushka Kraïna on the N. from the territories of the Hot and Klement tribes on the S.; leaving Gusinye and Plava to the S.E., it turns to the N.W. on reaching the Mokra Planina, and then follows the course of the Tara river. On the S., Albanian territory has been curtailed owing to the acquisition of the Arta district by Greece (May 1881), the river Arta now forming the frontier. On the E. the chains of Shar, Grammos, and Pindus constitute a kind of natural boundary which does not, however, coincide with ethnical limits, nor with the Turkish administrative divisions. Albania is inhabited by six different races: Albanians (who form the great majority), Serbs, Bulgars, Greeks, Vlachs, and Turks, together with an inconsiderable number of gypsies and Jews. The larger portion of the interior is occupied by a fairly compact Albanian population. Since about the year 1870 there has been a remarkable advance of the Albanians in a north-easterly direction towards Prishtina, Vrania, and Usküb, the invaders inflicting much injury on the Serb and Bulgar inhabitants. Servian settlements exist in various parts of Northern Albania; there is a strong Bulgarian colony in the neighbourhood of Dibra and Ochrida; farther south, Mount Zygos and the Pindus range—the "Great Wallachia" of the middle ages—are inhabited by Vlachs or *Tzintzars*; several Turkish settlements are found in the south-eastern districts, while in Southern Epiros there is a large admixture of the Greek element. North-western Albania forms part of the Turkish vilayet of Kossovo; the northern highlands are included in the vilayet of Shkodra (Scutari), the eastern portion of Central Albania belongs to the vilayet of Mon-

astir, and the southern districts are comprised in the vilayet of Iannina. The boundaries of the three last-named vilayets meet near Elbassan. The name Albania (in the Tosk dialect *Arberia*, in the Gheg *Arbenia*), like Albania in the Caucasus, Armenia, Albany in Britain, and Auvergne (*Arvenia*) in France, is probably connected with the root *alb, alp*, and signifies "the white or snowy uplands."

The mountain system is extremely complex, especially that of the northern region. On the E. the great Shar range, extending in a south-westerly direction from the neighbourhood of Prishtina to that of Dibra, is continued towards the S. by the ranges of Grammos and Pindos: the entire chain, a prolongation of the Alpine systems of Bosnia and Dalmatia, may be described as the backbone of the peninsula; it forms the watershed between the Aegean and the Adriatic, and culminates in the lofty peak of Liubotrn, near Kalkandele, the highest summit in South-Eastern Europe (3050 metres). The country to the W. of this natural barrier may be divided geographically into three districts—Northern, Central, and Southern Albania. The river Shkumb separates the northern from the central district, the Viossa the central from the southern. The highland region of Northern Albania is divided into two portions by the lower course of the Drin; the mountains of the northern portion, the Bieska Malziis, extend in a confused and broken series of ridges from Scutari to the valleys of the Ibar and White Drin; they comprise the rocky group of the Prokletia, or Accursed Mountains, with their numerous ramifications, including Mount Velechik, inhabited by the Kastrat and Shkrel tribes, Bukovik by the Hot, Golesh by the Klement, Skulsen (2296 metres), Baba Vrkh (about 2227 metres), Maranzh near Scutari, and the Bastrik range to the E. South of the Drin is another complex mountain system, including the highlands inhabited by the Mirdites and the Mat tribe; among the principal summits are Deia Mazzuklit, Mal-i Velesh, Kraba, and Toli. Central Albania differs from the northern and southern regions in the more undulating and less rugged character of its surface; it contains considerable lowland tracts, such as the wide and fertile plain of Musseki, traversed by the river Simen. The principal summit is Tomor (2413 metres), overhanging the town of Berat. Southern Albania, again, is almost wholly mountainous, with the exception of the plains of Iannina and Arta; the most noteworthy feature is the rugged range of the Tehika, or Khimara mountains, which skirt the sea-coast from S.W. to N.E., terminating in the lofty promontory of Glossa (ancient *Akrokeraunia*). Further inland the Mishkeli range to the N.E. of Lake Iannina and the Nemertzika mountains run in a parallel direction. In the extreme S., beyond the basin of the Kalamas, the mountains of Suli and Olyzika form a separate group. The rivers, as a rule, flow from E. to W.; owing to the rapidity of their descent none are navigable except the Boyana and Arta in their lower courses. The principal rivers are the Boyana, issuing from Lake Scutari, and consequently regarded as a continuation of the Montenegrin Moratcha,

Physical features.

the Drin, formed by the confluence of the White and Black Drin, which flowing respectively to the S. and N. through a long valley at the foot of the Shar range, take a westerly direction after their junction, the Matia, the Arzen, the Shkumb (anc. *Genusos*), the Simen (anc. *Apsos*), formed by the junction of the Devol and Ergene, the Viossa (anc. *Aösus*), which owing to the trend of the Chima range takes a north-westerly direction, the Kalamas (anc. *Thyamis*), and the Arta (anc. *Arachthos*), flowing S. into the Ambracian Gulf. A portion of the stream of the Drin has recently found its way into the Boyana channel; the result has been a rise in the level of Lake Scutari and the inundation of the adjacent lowlands. A proposal to confine the Drin to its former course by means of a dyke, and to ease the downflow of the Boyana by a canal opening navigation to Lake Scutari, has long been considered by the Turkish authorities. The great lakes of Scutari (350 sq. kil.) and Ochrida (270 sq. kil.) are among the most beautiful in Europe; the waters of the latter, which find an outlet in the Black Drin, are of marvellous clearness. Lake Malik, to the S.W. of Ochrida, is drained by the Devol. The waters of the picturesque Lake Iannina (61 sq. kil.) find an issue by *katabothra*, or underground channels, into the Ambracian Gulf. The lake of Butrinto (anc. *Buthrotum*) is near the sea-coast opposite Corfu.

The climate is healthy in the uplands, though subject to violent changes; in the valleys fever is very prevalent, especially in the basins of the Boyana, the lower Drin, and the Simen. The winter is short, but exceedingly cold; snow remains on the Prokletia and other mountains till August, and sometimes throughout the year. The summer temperature in the plains is that of southern Italy; in the mountain districts it is high during the day, but falls almost to freezing-point at night. The sea-coast is exposed to the fierce *bora*, or north wind, during the spring.

The mountains of Albania are said to be rich in minerals, but this source of wealth remains practically unexplored.

Natural products. Iron and coal are probably abundant, and silver-lead, copper, and antimony are believed to exist. Gold mines were worked in antiquity in the Drin valley, and silver mines in the Mirdite region were known to the Venetians in the middle ages. At Selinitza, near Avlona, there is a remarkable deposit of mineral pitch which was extensively worked in Roman times; mining operations are still carried on here, but in a somewhat primitive fashion. The splendid forests, of which there are 70,000 square acres in the vilayet of Scutari alone, are undergoing a rapid process of destruction, as in other lands under Turkish rule. The principal trees are the oak, the valonia oak, the beech, ash, elm, plane, celtis, poplar, and walnut, which give way in the higher regions to the pine and fir. The oak forests near Dibra, where charcoal-making is a considerable industry, and the beech-woods of the Prishtina district, are especially remarkable. The sumach is largely grown in the Mirdite

district; its leaves are exported to Trieste for use in tanneries and dyeworks. In 1898 the export of valonia was estimated at 280,000 francs, of sumach at 60,000 francs. Of fruit-trees the white mulberry, cherry, and wild pear are plentiful; the chestnut and walnut are sometimes met with, and the olive is grown in the lowland and maritime districts. The exportation of olive oil in 1898 was

SKETCH MAP OF ALBANIA.

valued at 600,000 francs. The greater part of the country is admirably suited to viticulture, and wine of tolerable quality is produced. Tobacco is grown extensively in Southern Albania, especially near Berat and in the upper valley of the Viossa, but the quantity exported is small. The means of subsistence are mainly provided by the cultivation of grain and cattle-rearing. Notwithstanding the primitive condition of agriculture,

the deficiency of communications, and the damage caused by frequent inundations, Albania furnishes almost the entire corn supply of the Dalmatian coast and islands. Maize is the favourite grain for home consumption, but considerable quantities of this cereal, as well as barley, rye, and oats, are exported. The total export of cereals in 1898 was valued at 1,770,000 francs. Sheep and goats form almost the only wealth of the mountaineers of Northern Albania; large cattle are found only on the plains. The slopes of Pindos afford excellent pasture for the flocks of the Vlakh shepherds. The export of raw hides and wool is considerable; the former was estimated in 1898 at 2,260,000 francs, the latter at 600,000 francs. The lakes and rivers of Albania abound in fish. The *scoranze*, a kind of sardine, is taken in great quantities in Lake Scutari; it is salted and smoked for home consumption and exportation. Sea fishing is almost wholly neglected. There are salines at Avlona and other places on the coast.

The exports in 1898 were estimated at 12,000,000 francs, the imports at 34,000,000 francs, the former comprising agricultural produce, live stock, hides, wool, cheese, eggs, poultry, olive oil, valonia, sumach leaves, timber, skins of wild animals, silk, tobacco, and salted fish, the latter manufactured articles, cloth, hardware, furniture, firearms, gunpowder, sugar, coffee, etc. The monopoly of Albanian commerce formerly possessed by Venice has descended to Austria-Hungary; the trade with other countries, except Italy, is inconsiderable. Owing to the poverty of the people, cheap Austrian goods find a readier sale than the more expensive and solid British manufactures. The maritime traffic is largely conducted by the steamers of the subsidized Austrian-Lloyd company, Trieste being the principal commercial centre; the coasting trade is carried on by small Greek and Turkish sailing vessels. The trade of the northern and western districts has to some extent been diverted to Salonika since the opening of the railways from that town to Mitrovitza and Monastir. The development of commerce is retarded by lack of communications; the country possesses no railways and few roads. Several railway lines have been projected, but there is no great probability of their construction under existing political conditions. The Via Egnatia, the great Roman highway to the east, is still used; it runs from Durazzo (*Dyrrhachium*) to Elbassan and Ochrida. Iannina is connected by carriage-roads with Monastir, Agii Saranta, and Preveza. As a rule, however, bridle-paths supply the only means of communication. The native industries are inconsiderable, and many of them are in a languishing condition. The manufacture of highly ornate firearms, yataghans, and other weapons at Scutari, Gyakovo, and Prizren has declined, owing to the importation of modern rifles and revolvers. Gold and silk embroidery, filigree work, morocco, and richly-braided jackets are produced for home use and for sale in Bosnia, Macedonia, and Montenegro.

The population of Albania may be estimated at between 1,600,000 and 1,500,000, of whom 1,200,000 or 1,100,000 are Albanians. Of the other races the Slavs (Serbs and Bulgars) are the most numerous, possibly numbering 250,000. There is a considerable Greek-speaking population in Epiros (including many Mahommedan Albanians), which must, however, be distinguished from the genuine Greeks of Iannina, Preveza, and the extreme south; the latter may be estimated at 100,000. The Vlaks, mainly in the Pindos district, possibly number 70,000. The population of the vilayet of Scutari is given as 322,000, or 28 per square kilometre; that of the vilayet of Iannina as 648,000, or 33 per square kilometre. The principal towns are Scutari (Albanian

Shkóder, with the definite article *Shkóder-a*), the capital of the vilayet of that name, pop. 37,000; Prizren, 30,000; Iannina (often incorrectly written *Ioannina*), capital of the southern vilayet, 25,000; Gyakovo, 25,000; Dibra, 20,000; Ipek (Slav. *Petch*), 15,000; Berat, 15,000; Ochrida, 15,000; Tirana, 12,000; Argyrokaastro, 11,000; Kortcha (Slav. *Goritza*), 10,000; Elbassan (perhaps anc. *Albanopolis*), 8000; Metzovo, 7500; Préveza, 6500; and Kroia, the ancient fortress of Skanderbeg, 5000.

The Albanians are apparently the most ancient race in South-Eastern Europe. History and legend afford no record of their arrival in the Balkan peninsula. They are probably the descendants of the earliest Aryan immigrants, who were represented in historical times by the kindred Illyrians, Macedonians, and Epirots; the Macedonians and Epirots are believed by Hahn to have formed the core of the pre-hellenic Tyrrheno-Pelasgian population which inhabited the southern portion of the peninsula and extended its limits to Thrace and Italy. The Illyrians were also "Pelasgian," but in a wider sense. Of these cognate races, which are described by the Greek writers as barbarous or non-hellenic, the Illyrians and Epirots, he thinks, were respectively the progenitors of the *Ghegs*, or northern, and the *Tosks*, or southern, Albanians. The Via Egnatia, which Strabo (vii. fragment 3) describes as forming the boundary between the Illyrians and Epirots, practically corresponds with the course of the Shkumb, which now separates the Ghegs and the Tosks. The same geographer (v. 2, 221) states that the Epirots were also called Pelasgians; the Pelasgian Zeus was worshipped at Dodona (Homer, *Il.* xvi. 234), and the neighbourhood of the sanctuary was called Pelasgia (Herodotus, ii. 56). The name *Tosk* is possibly identical with *Tuscus*, *Etruscus*, while the form *Tyrrhenus* perhaps survives in Tirana. The large number of Slavonic local names in Albania, even in districts where no trace of a Slavonic population exists, bears witness to an extensive Servian or Bulgarian immigration in the early middle ages, but the original inhabitants appear to have gradually ousted the invaders. The determination with which this remarkable race has maintained its mountain stronghold through a long series of ages has hitherto met with scant appreciation in the outside world. While the heroism of the Montenegrins has been lauded by writers of all countries, the Albanians—if we except Byron's eulogy of the Suliots—still *carent vate sacro*. Not less noticeable is the tenacity with which isolated fragments of the nation have preserved their peculiar characteristics, language, customs, and traditions. The Albanians in Greece and Italy, though separated for six centuries from the parent stock, have not yet been absorbed by the surrounding populations.

The Albanians, both Ghegs and Tosks, call themselves *Shkypetar*, and their land *Shkypenia* or *Shkypieria*, the former being the Gheg, the latter the Tosk form of the word. *Shkypetar* has been variously interpreted. According to Hahn it is a participial form from *shkypōy* "I understand," signifying "he who knows" the native language; others interpret it as "the rock-dweller," from *shkep*, *shkip*, "rock." The designations *Arber* (Greek *Αρβανίτης*, Turkish *Arnaout*) denoting the people, and *Arberia* or *Arberia* the land, are also, though less frequently, used by the Albanians. The Tosk form *Arberia* strictly applies only to the mountain district near Avlona. The region inhabited by a more or less homogeneous Albanian population may be roughly marked out by a line drawn from the Montenegrin frontier at Berane to Leskovatz in Servia, thence to Vrania, Uskub, Prilep, Monastir, Florina, Kastoria, Iannina, and Parga. These limits, however, are far from including all the members of a widely-scattered race. The Albanians in Greece, whose settlements extend over Attika, Bœotia, the district of Corinth, and the Argolid peninsula, as well as Southern Eubœa and the islands of Hydra, Spetzæ, Poros, and Salamis, descend from Tosk immigrants in the 14th century. They played a brilliant part in the war of independence, and to-day supply the Greek army with its best soldiers. They were estimated by Leake at 200,000. A large number still speak the Albanian language; many of the older men, and a considerable proportion of the women, even in the neighbourhood of Athens, are ignorant of Greek. The Albanian settlements in Southern Italy and Sicily were founded in

1444, 1464, and 1468; minor immigrations followed in the three succeeding centuries. In Southern Italy there are 72 Albanian communes, with 154,674 inhabitants; in Sicily 7 communes, with 52,141 inhabitants. The Italian and Sicilian Albanians are of Tosk descent, and many of them still speak a variation of the Tosk dialect. There are also several Albanian settlements in European Turkey and Asia Minor, some founded by military colonists who received grants of land from successive sultans, others owing their origin to enforced migrations after insurrections in Albania. The only genuine division of the Albanian race is that of Ghegs and Tosks; the Liaps, who inhabit the district between the Viossa and the sea, and the Tshams or Chams, who occupy the coast-land south of the Kalamas, are subdivisions of the Tosk family. The name Gheg (*Gëgë-a*) is not adopted by the Ghegs themselves, being regarded as a nickname; the designation Tosk (*Toskë-a*) is restricted by the Tosks to the inhabitants of a small region north of the lower Viossa (Toskeria).

While the other primitive populations of the peninsula were either hellenized or latinized, or subsequently

absorbed by the Slavonic immigration, the Albanians to a great extent remained unaffected by foreign influences. Retaining their original language and preserving the customs and institutions of remote antiquity, they present a distinct type, and differ in many essential particulars from the other nations of the peninsula. The Ghegs, especially, notwithstanding their fierce and lawless character, their superstition, ignorance, and predatory propensities possess some noteworthy qualities rarely found in Eastern Europe: simple, brave, faithful, and sometimes capable of devoted attachment, these wild mountaineers make excellent soldiers and trustworthy retainers; they have long furnished a bodyguard to the sultan, and are much employed as kavasses and attendants at foreign embassies and consulates in the East. The native disposition of the Tosks has been modified by intercourse with the Greeks and Vlaks; while the Gheg devotes his attention exclusively to fighting, robbery, and pastoral pursuits, the Tosk occasionally occupies himself with commercial, industrial, or agricultural employments; the Gheg is stern, morose, and haughty, the Tosk lively, talkative, and affable. The natural antipathy between the two sections of the race, though less evident than in former times, is far from extinct. In all parts of Albania the vendetta (*gyāk*) or blood-feud, the primitive *lex talionis*, is an established usage; the duty of revenge is a sacred tradition handed down to successive generations in the family, the village, and the tribe. A single case of homicide often leads to a series of similar crimes or to protracted warfare between neighbouring families and communities; the murderer, as a rule, takes refuge in the mountains from the avenger of blood, or remains for years shut up in his house. It is estimated that in consequence of these feuds scarcely 75 per cent. of the population die a natural death. A truce (*bessa*: literally "faith, pledge"), either temporary or permanent, is sometimes arranged by mediation or, among the Ghegs, by the intervention of the clergy; a general *bessa* has occasionally been proclaimed by special iradé of the sultan, the restoration of peace being celebrated with elaborate ceremonies. So stringent are the obligations of hospitality that a household is bound to exact reparation for any injury done to a guest as though he were a member of the family. No traveller can venture into the mountain districts without the *bessa* of one of the inhabitants; once this has been obtained he will be hospitably welcomed. In some districts there is a fixed price of blood; at Argyrokastro, for instance, the compensation

paid by the homicide to the relatives of his victim is 1200 piastres (about £10), at Khimara 2000 piastres; once the debt has been acquitted amicable relations are restored. Notwithstanding their complete subjection, women are treated with a certain respect, and are often employed as intermediaries in the settlement of feuds; a woman may traverse a hostile district without fear of injury, and her *bessa* will protect the traveller or the stranger. Women accompany their male relatives to the battlefield for the purpose of tending the wounded and carrying away the dead. The bride brings no dowry to her husband; she is purchased at a stipulated price, and earnest-money is paid at the betrothal, which usually takes place while the contracting parties are still children. It is customary for young men who are attached to each other to swear eternal brotherhood (compare the Slavonic *pobratimstvo*); the contract is regarded as sacred, and no instance has been known of its violation. The costume of the Tosks differs from that of the Ghegs; the distinctive feature of the former is the white plaited linen fustanella or petticoat, which has also been adopted by the Greeks; the Ghegs wear trews of white or crimson native cloth adorned with black braid, and a short, close-fitting jacket, which in the case of wealthy persons is embellished with gold lace. The fez is worn by both races, and in the northern highlands yataghans and firearms are almost invariably carried. The costume of the Mirdite and Mat tribes is peculiar. It consists of a sheepskin cap, a long white tunic bound with a red girdle, white linen trousers, and opinki, or sandals.

The tribal organization in Northern Albania is an interesting survival of the earliest form of social combination; it may be compared in many respects with that which existed in the Scottish highlands in the time of the Stuart kings. The practical autonomy which the Gheg mountaineers enjoy has been won by a prolonged and successful resistance to Turkish domination; as a rule they pay no taxes, they are exempt from the conscription, they know nothing of the Ottoman law, and the few Turkish officials established amongst them possess no real authority. Their only obligation to the Turkish government is to furnish a contingent in time of war; the only law they recognize is either traditional custom (*adët*) or the unwritten *Kanun-i Leks Dukajinit*, a civil and criminal code, so called from its author, Leka Dukajini, who is supposed to have lived in the 13th or 14th century. The tribe or *mal* ("mountain") is often composed of several clans (*phis-i pharea*) or *baryaks* (literally "standards") each under a chief or *baryaktar* (standard-bearer), who is, strictly speaking, a military leader; there are in each clan a certain number of elders or voivodes (Albanian *kru-ye*, pl. *krene-te*) who form a council and, like the *baryaktar*, hold their office by hereditary right; they preside over the assemblies of the tribesmen, which exercise the supreme legislative power. The clan is generally subdivided into smaller communities (*mahale*), each administered by a local notable or *gyobar*. The *gyobars* superintend the execution of the laws, collect fines, and administer capital punishment; they are in contact with the *bublik-pashi*, or resident representative of the tribe at Scutari, who forms the only link between the mountaineers and the Turkish government. He communicates to the tribesmen the orders of the Vali, which must be framed in accordance with their customs and institutions. The tribes of Northern Albania, or Ghegeria, may be classified in seven groups as follows:—(1) The Mirdites, who inhabit the alpine region around Orosh to the south-east of Scutari—the most important of all in respect of numbers (about 26,000) and political independence. A Catholic tribe, occupying an inaccessible

Tribal system.

district, they have hitherto defeated every effort of the Turks to encroach on their autonomy. Their hereditary chiefs or *capidans*, belong to the family known as *Dera e Gyon Markut* (the house of John Marco) which is said to be descended from Skanderbeg. In 1868 the reigning chief, Bib Doda, died, and his son and successor Prenk was detained as a hostage by the Turks. The Mirdites consequently refused to contribute their customary contingent to the Turkish army, and eventually Prenk was restored. His ambiguous conduct, however, led to the despatch of two expeditions against the Mirdites and the devastation of their territory. In 1880 Prenk was kidnapped by the Turkish authorities and exiled to Anatolia; another member of the ruling family was appointed kaimakam, but the Mirdites refused to obey him, and their district has ever since been in a state of anarchy. No Moslem is allowed to remain in Mirdite territory.

(2) The Mi-shkodrak (Upper Scutari) group or confederation, also known as the Malsia-Madhé (Great Highlands) is composed of the Klement, Grud-a Hot, Kastrat, and Shkrel tribes, which occupy the mountainous district north-east of Scutari. Owing to the proximity of the capital this group is comparatively subject to the Turkish power, and pays a small annual tribute; the chiefs, who assess and collect the tribute, form a kind of administrative council; the confederation has also an official representative council at Scutari, called the *Jibal*, under the presidency of a *Serkardé* or Moslem official.

(3) The Dukajin, whose territory lies between that of the last-named group and the Mirdite country, include the Pulati, Shalla, Shoshi, and other tribes; they are more independent and more savage than the Mi-shkodrak, and have never paid tribute from time immemorial.

(4) The Puka group, known as "the Seven Baryaks of Puka," dwell farther to the east; they are nominally administered by a Turkish kaimakam, who is a mere spectator of their proceedings.

(5) The Malsia Gyakovs, a group of two Catholic and three Moslem tribes, extend in the direction of Gyakovo, where they maintain an official representative; they are entirely exempt from taxation.

(6, 7) The Malsia-Lezhs, who occupy the Alessio highlands, and the Malsia Krues, who inhabit the region north of Kroia, live in a state of extreme poverty and pay no tribute; the latter are much addicted to brigandage. To these seven groups, which are included under the general appellation of *Malsiori*, or "highlanders," may be added the Malsia of Dibra, who extend to the west and north of that town, and form a large separate group; they are notorious for their fierce lawless character, and maintain themselves by plundering the Bulgarian peasants in their neighbourhood. In general the attitude of the Albanians in the north-western districts towards the Slavonic peasantry may be compared with that of the Kurds towards the Armenians. In Central Albania the Mat tribe, which occupies the upper valley of the Matia, presents an entirely different organization; their district is governed by four wealthy families possessing hereditary rank and influence. Towards the south the tribal organization becomes looser and is gradually supplanted by a kind of feudal system; among the powerful aristocratic houses may be mentioned the Vliores at Avlona, who are stated to own 400 square kilometres of land, and the Toptans at Tirana. The principal landowners, who reside in fortified houses, are all Moslems; their estates are cultivated on the *metayer* system. Since the time of Ali Pasha, who broke the power of the local chieftains, Southern Albania has been subject to the central Turkish power; before that period the mountaineers of Suli and Khimara enjoyed an independence similar to that of the Gheg tribes.

The great majority of the Albanians, probably more

than three-fifths, are Moslems. The conversion of the Christian population to Islam appears to have taken place during the 16th and 17th centuries. **Religions.** Like the Cretan Moslems and the Bulgarian Pomaks, the Albanian Mahommedans retain many Christian traditions and customs; it is said that many thousands of them secretly adhere to their original faith. In the vilayet of Scutari they form more than 60 per cent. of the population; Central Albania is almost entirely Moslem; in Southern Albania, however, there is a considerable Christian population, whose limits practically coincide with those of the Greek-speaking districts. Of the Christian Albanians (about 480,000) some 100,000 are Catholics, almost all belonging to the Gheg tribes of the north; the remainder, including a small proportion of the Tosks, and nearly all the Greeks, Slavs, and Vlachs, are of the Orthodox Church. The Catholic Ghegs appear to have abandoned the Eastern for the Western Church in the middle of the 13th century. Their bishops and priests, who wear the moustache in deference to popular prejudice, are typical specimens of the church militant. Some of the Gheg tribes, such as the Puka, Malsia, Gyakovs, and Malsia Krues, are partly Catholic, partly Moslem; among fellow-tribesmen the difference of religion counts for little. The Mirdites are exclusively Catholic, the Mat-i exclusively Moslem. At the head of the Catholic hierarchy are the archbishops of Scutari (with three suffragans), Prizren, and Durazzo; the mitred abbot of St Alexander is the spiritual chief of the Mirdites. The Orthodox Church has metropolitans at Prizren, Durazzo, Berat, Iannina, and Kortcha; the Bulgarian exarchate maintains a bishop at Dibra. Of the Albanians in Sicily the great majority (44,791) remain faithful to the Greek Church; in Italy 116,482 follow the Latin ritual, and 38,192 the Greek. All the Albanians in Greece belong to the Orthodox Church.

Education is almost non-existent, and the vast majority of the population, both Christian and Moslem, are totally illiterate. Instruction in the Albanian language is prohibited by the Turkish Government for political reasons; a single exception has been made in the case of an American school for girls at Kortcha. There are Turkish primary and secondary schools in some of the towns; in the village mosques instruction in the Koran is given by the imâms, but neither reading nor writing is taught. The aristocratic Moslem families send their sons to be educated in Constantinople or Vienna. At Scutari a college and a seminary are maintained by the Jesuits, with the aid of the Austrian Government; the Franciscans have several primary schools, and three lay schools are supported by the Italian Government: in all these institutions Italian is the language of instruction. There are two Servian seminaries at Prizren. In Southern Albania there are Greek schools in the towns and a large Greek gymnasium at Iannina. The priests of the Greek Church on whom the rural population depend for instruction, are often deplorably ignorant. The merchant families of Iannina are well educated; the dialect spoken in that town is the purest specimen of colloquial Greek.

Albania has never had a national history, owing to the want of unity and cohesion amongst its inhabitants; even the heroic resistance of Skanderbeg to the Turks (1443-67) can hardly be described as a great national effort. The surrender of Scutari in 1478 marked the end of Venetian supremacy in Upper Albania; many of the native Christian defenders of the town eventually took refuge in the mountains, and became, it is said, the ancestors of the Catholic Ghegs. Notwithstanding the abandonment of Christianity by a large section of the population, the authority of the sultans was never effectively established, and succeeding centuries

Recent history.

present a record of interminable conflicts between the tribesmen and the Turks, between the Christians and the converts to Islam, or between all combined and the traditional Montenegrin enemy. The decline of the Ottoman power, which began towards the end of the 17th century, was marked by increasing anarchy and lawlessness in the outlying portions of the empire. A Moslem chieftain, Mehemet of Bushat, after obtaining the pashalik of Scutari from the Porte, succeeded in establishing an almost independent sovereignty in Upper Albania, which remained hereditary in his family for some generations. In Southern Albania Ali Pasha of Tepelen (*b.* about 1750), an able, cruel, and unscrupulous man, subdued the neighbouring pashas and chiefs, crushed the Suliotes and Khimarrhotes, and exercised a practically independent sovereignty from the Adriatic to the Ægean. He introduced comparative civilization at Iannina, his capital, and maintained direct relations with foreign powers. Eventually he renounced his allegiance to the Sultan, but was overthrown by a Turkish army in 1822. Shortly afterwards the dynasty of Scutari came to an end with the defeat of Mustafa Pasha, the last of the house of Bushat. The opposition of the Albanians, Christian as well as Moslem, to the reforms introduced by the Sultan Mahmūd II. led to the devastation of the country and the expatriation of thousands of its inhabitants. During the next half-century several local revolts occurred, but no movement of a strictly political character took place till after the Berlin Treaty (13th July 1878), when some of the Moslems and Catholics combined to resist the stipulated transference of Albanian territory to Austria-Hungary, Servia, and Montenegro, and the *Albanian League* was formed by an assemblage of chiefs at Prizren. The movement, which was instigated by the Porte with the object of evading the provisions of the treaty, was so far successful that the restoration of Plava and Gusinye to Albania was sanctioned by the Powers, Montenegro receiving in exchange the town and district of Dulcigno. The Albanian leaders, however, soon displayed a spirit of independence, which proved embarrassing to Turkish diplomacy and caused alarm at Constantinople; their forces came into conflict with a Turkish army under Dervish Pasha near Dulcigno (November 1880), and eventually the league was suppressed. A similar agitation on a smaller scale was organized in Southern Albania to resist the territorial concessions awarded by the Powers to Greece. These movements, however, were far from displaying a genuinely national character. In recent years attempts have been made by Albanians resident abroad to propagate the national idea among their compatriots at home; committees have been formed at Brussels, Bucharest, Athens, and elsewhere, and books, pamphlets, and newspapers are surreptitiously sent into the country. Unity of aim and effort, however, seems foreign to the Albanians, except in defence of local or tribal privileges. The growth of a wider patriotic sentiment will depend on the spread of popular education: up to the present no appreciable progress has been made in this direction.

Albania abounds in ancient remains, which as yet have been little explored. Fragments of Cyclopean structures were discovered by Hahn at Kretzunista, Arinista, and other sites in the district of Argyrokastro; the walls, partly Cyclopean, of an ancient city (perhaps *Bullis*) are visible at Gradista on the Viossa. The remains of the classical epoch attest the influence of Roman rather than of Greek civilization. At Pollina, the ancient *Apollonia*, are the remnants of a Doric temple, of which a single column is still standing. A little north of Preveza are the considerable ruins of Nikopolis, founded by Octavian to commemorate the victory of Actium. At Khimara (ancient *Chimæra*) the remains

of an old Greek city may still be seen; at Santa Quaranta (ancient *Onchesmos*) the walls and towers of a later town are in good preservation. Few traces remain of the once celebrated Dyrrhachium. The ruins of Pandosia, Ephyra, Elatea, Phœniké, Buthrotum, Akrolissos, and other towns may be identified. The most important and interesting remains, however, are those of Dodona, near Iannina, the seat of the famous oracle of the Pelasgian Zeus. The ruins, which were excavated by Mr Constantine Carapanos of Athens in 1875, furnished a rich yield of inscriptions, statuettes, vases, and other objects. The temple of Zeus stood in the upper part of a *temenos* or sacred precinct, together with two other buildings, one of which was probably a sanctuary of Aphrodite; the inclosure was approached by propylæa. A remarkably large theatre is situated in a neighbouring valley. For details see Mr Carapanos's work, *Dodone et ses Ruines* (Paris, 1878). Of the mediæval ruins those of Kroia, the stronghold of Skanderbeg, are the most interesting.

Albanian is peculiarly interesting as the only surviving representative of the so-called Thracio-Illyrian group of languages which formed the primitive speech of the peninsula. It has afforded an attractive study to philologists, amongst whom may be mentioned Malte-Brun, Leake, Xylander, Hahn, Miklositch, and G. Meyer. The analysis of the language presents great difficulties, as, owing to the absence of literary monuments, no certainty can be arrived at with regard to its earlier forms and later development. The groundwork, so far as it can be ascertained, and the grammar are Indo-European, but a large number of words have been borrowed from the Latin, or Italian, and Greek, and it is not always easy to decide whether the mutilated and curtailed forms now in use represent adopted words or belong to the original vocabulary. There is also a considerable admixture of Turkish and Slavonic words. Notwithstanding certain points of resemblance in structure and phonetics, Albanian is entirely distinct from the neighbouring languages; in its relation to early Latin and Greek it may be regarded as a co-ordinate member of the Aryan stock. It possesses seven vowels; among the consonants are the aspirated *d* and *t*, as in Greek, and many other sounds, such as *b*, *d*, *sh*, *zh* (French *j*), and hard *g*, which are wanting in Greek, but exist in the Slavonic languages. There are three declensions, each with a definite and indefinite form; the genitive, dative, and ablative are usually represented by a single termination: the vocative is formed by a final *o*, as *memmo* from *memme*, "mother." The neuter gender is absent. There are two conjugations; the passive formation, now wanting in most Indo-European languages, has been retained, as in Greek: thus *kerko-iy*, "I seek," forms *kerko-n-em*, "I am sought." The infinitive is not found; as in Greek, Rumanian, and Bulgarian it is replaced by the subjunctive with a particle. The two auxiliary verbs are *kâm*, "I have," and *yâm*, "I am." An interesting and characteristic feature of the language is the definitive article, which is attached to the end of the word: e.g., *mik* ("friend," *amicus*), *mik-u* ("the friend"); *kien* ("dog"), *kein-i*; *Shkumb*, *Shkumb-i*. The suffix-article likewise appears in Rumanian and Bulgarian, but in no other Latin or Slavonic language. Another remarkable analogy between the Albanian and the neighbouring languages is found in the formation of the future; the Albanian *do* (3rd pers. sing. of *dova*, "I will,") like the Greek *θα*, is prefixed without change to all persons of the verb: a similar usage in Servian and Bulgarian, as well as in Rumanian (especially the Macedonian dialect), is peculiar to these languages in the Slavonic and Latin groups. These and other points of similarity have led to the conjecture that the primitive

Illyrian language may have exerted some kind of influence on the other idioms of the peninsula. In the absence of literary culture the Albanian dialects, as might be expected, are widely divergent; the limits of the two principal dialects correspond with the racial boundaries of the Ghegs and Tosks, who understand each other with difficulty: the Albanians in Greece and Italy have also separate dialects. In writing Albanian the Latin character is employed by the Ghegs, the Greek by the Tosks; neither alphabet suffices to represent the manifold sounds of the language, and various supplementary letters or distinguishing signs are necessary. In the use of these no uniform system has yet been adopted. An alphabet of fifty-two letters, some presenting ancient Phœnician and Cretan forms, was found by Hahn in partial use at Elbassan and Tirana; its antiquity, however, has not been established. The Tosks generally use the Greek language for written communications. The native folklore and poetry of the Albanians can hardly compare with that of the neighbouring nations in originality and beauty. The earliest printed works in Albanian are those of the Catholic missionaries; the first book containing specimens of the language was the *Dictionarium Latino-Epiroticum*

of Bianchi, printed in 1635. The literature of the last two centuries consists mainly of translations and religious works written by ecclesiastics, some of whom were natives of the Albanian colonies in Italy. The most noteworthy Albanian writer was Girolamo di Rada (b. 1815), a poet, philologist, and collector of national folklore. Among his successors may be mentioned Vincenzo Dorsa and Demetrio Camarda.

(J. D. B.)

Albany, a river of Canada, forming part of the boundary between Ontario and Keewatin, rises in Lake St Joseph in (head of lake) long. 91° 25' W. and lat. 50° 55' N., and falls into James Bay, its total length being upwards of 500 miles. There are four Hudson's Bay Company's posts on its banks. The Ogoki and Kenogami rivers are the principal tributaries.

Albany, the capital of New York state, and of Albany county, U.S.A., situated in 42° 40' N. lat. and 73° 45' W. long., on Hudson river, just below the mouth of Mohawk river. The mean annual temperature is 49°, and the annual rainfall is 40 inches. The death-rate, 20-90 per thousand in 1900, is more than that of the country at large and the average of large cities. The plan of the city presents considerable regularity, although its site, rising sharply from the river in bluffs, is by no means level. The city is divided into nineteen wards, and is supplied with water by pumping from Hudson river and smaller streams, the water-works being owned by the city. The streets are broad, about half of them paved, mainly with granite blocks and cobble stones, and the drainage is fairly good. The fire and police equipment are good. The finest of the many public buildings is the magnificent new state Capitol, situated at the summit of State Street Hill. It is built of granite, enclosing a court, and is 300 by 400 feet on its ground plan. It is not yet entirely completed, but its estimated cost is \$25,000,000. The city contains many educational and scientific institutions. It is entered by four railways—the Boston and Albany, the New York Central and Hudson River, the Delaware and Hudson, and the West Shore. It is also the terminus of the Erie and Champlain canals, and is near the head of navigation on the Hudson river. These various avenues of communication give it a large commerce by rail, canal, and river. Numerous steamboat lines connect it with New York and other river points. It is a manufacturing city of importance, having in 1890 \$17,270,000 invested capital, employing 15,041 persons, and its products were valued at \$25,531,000. The assessed valuation of property, real and personal, in 1898 was \$66,685,000, and the debt of the municipality \$3,294,000. The tax-rate, city, county, and state, was \$20.60 per thousand dollars. The popula-

tion in 1880 was 90,758; in 1890 it was 94,923, and in 1900 it was 94,151.

Albany, a city of Georgia, U.S.A., the capital of Dougherty county, situated in the south-western part of the state, on Flint river, at an altitude of 232 feet. It is in the midst of an agricultural region producing cotton and corn, for which this city serves as a supply point. It is a railway centre of importance, being entered by the Plant System, the Georgia and Alabama, the Central of Georgia, and the Albany and Northern railways. The population in 1880 was 3216, in 1890 it was 4008, and in 1900 it was 4606.

Albany, a municipality in West Australia, on King George Sound, 352 miles by rail, and 254 miles by road S.S.E. of Perth, in the county of Plantagenet. It is a port of call for the Peninsular and Oriental Company's and the Orient Company's steamers carrying the Australian mails, and also for those of the Messageries Maritimes and N. G. Lloyd steamers. This town is the health resort of the state. Its harbour is one of the finest on the Australian coast, and is well protected from winds. Defence works have been carried out at King George Sound and Princess Royal Harbour. The climate is very fine, and a scheme for a pure water supply is being devised. The Marine Drive, 5½ miles in circuit, was completed in 1898. Mean temperature (six years) for the year 58.6° F.; for February, 66.1° F.; for July, 52.6° F.; rainfall, 35.55 inches. The population in 1881 was 1024; in 1891, 2665; in 1900 about 3250.

Albany, Leopold George Duncan Albert, DUKE or, eighth child and youngest son of Queen Victoria, was born 7th April 1853. The delicacy of his health seemed to mark him out for a life of retirement, and as he grew older he evinced much of the love of knowledge, the capacity for study, and the interest in philanthropic and ecclesiastical movements which had characterized his father, the Prince Consort. He matriculated at Christ Church, Oxford, in November 1872, living with his tutor at Wykeham House, St. Giles's, and diligently pursued his favourite studies of science, art, and the modern languages. In 1876, he left the University with the honorary degree of D.C.L., and resided at Boyton

House, Wiltshire, and afterwards at Claremont. On coming of age in 1874, he had been made a Privy Councillor, and granted an annuity of £15,000. He travelled on the Continent, and in 1880 visited the United States and Canada. He was a trustee of the British Museum, a bencher of Lincoln's Inn, and continued to take an active part in the promotion of education and knowledge generally. Like his father and other members of his family, he was an excellent public speaker. On 24th May 1881 he was created Duke of Albany, Earl of Clarence, and Baron Arklow. On 27th April 1882, he married Hélène Frederica Augusta, princess of Waldeck-Pyrmont, and his income was raised by Parliament to £25,000. Having gone to the south of France for his health in the spring of 1884, he was attacked by a fit, the cause or the consequence of a fall in a club-house at Cannes, on 27th March, and died very unexpectedly on the following morning. His death was universally regretted, from the gentleness and graciousness of his character, and the desire and ability he had shown to promote intellectual interests of every kind. He left a daughter, born in February 1883, and a posthumous son, born 19th July 1884, who succeeded to the dukedom of Albany, and who on 30th July 1900 became duke of Saxe-Coburg on the death of his uncle. (R. G.)

Albay, a town of 34,000 inhabitants, on the eastern coast of Luzon, Philippine Islands, and capital of the province of Albay. Well built, with good government and public buildings, it was badly injured by fire in 1900. It is at the centre of one of the most important hemp-producing districts, and ships large quantities of this product to Manila. Other exports are rice, Indian corn, sugar, copra, and cloth made from hemp or from sinamay. It is near the foot of Mayon volcano, and in the year 1714 was completely destroyed during a violent eruption. The language is Bicol.

Albemarle, George Thomas Keppel, SIXTH EARL OF (1799-1891), British general, second son of the fourth earl, was born on 13th June 1799. Educated at Westminster-school, he entered the army as ensign, 14th Foot, in 1815. He joined his regiment in Belgium, and took part in the Waterloo campaign and the march to Paris, joined the second battalion in Corfu and was transferred to the 22nd Foot, with which he served in Mauritius and at the Cape, returning home in 1819, when he was appointed equerry to the duke of Sussex. Promoted to a lieutenancy in the 24th Foot, he was transferred to the 20th Foot, and went to India, where he was aide-de-camp to the marquis of Hastings until his resignation in 1823, when Keppel returned to England, travelling overland through Persia, Moscow, and St Petersburg. He published in 1825 an account of his travels, entitled *Journey from India to England*. He was aide-de-camp to the Marquess Wellesley, lord-lieutenant of Ireland, for two years, was promoted captain in the 62nd Foot, studied in the senior department of the Royal Military College at Sandhurst, and in 1827 obtained a half-pay unattached majority. He did not again serve on full pay, but rose to be a general. In 1829 he visited the seat of the Russo-Turkish war and was with the British fleet in Turkish waters. In 1832 he was returned in the Whig interest to the first reformed parliament as member for East Norfolk, and sat until 1835. He was private secretary to the premier, Lord John Russell, in 1846, and M.P. for Lynton from 1847 to 1849. He succeeded to the title on the death of his brother in 1851. He died in 1891, and was buried at Quiddenham, Norfolk. He wrote an account of a *Journey across the Balkans*, *Memoirs of the Marquess of Rockingham*, and an autobiography entitled *Fifty Years of My Life*. (R. H. V.)

Albert, formerly ANCRE, a town of France, arrondissement of Peronne, department of Somme, 16 miles N.E. by E. of Amiens, on railway from Paris to Amiens. The town stands on a branch of the Ancre, which here forms a pretty cascade. There are large and important engineering establishments of every kind. Population (1881), 5374; (1891), 5941; (1896), 6433, (comm.) 6651.

Albert, Frederick Augustus, KING OF SAXONY (1828—), was born 23rd April 1828, being the eldest son of Prince Johann, who succeeded to the throne in 1854. His education was, as is usual with German princes, to a great extent military, but he attended lectures at the university of Bonn. His first experience of warfare was in 1849, when he served as a captain in the campaign of Schleswig-Holstein against the Danes. When the war of 1866 broke out, Saxony, which had for many years under the ministry of Beust adopted an anti-Prussian policy, was the most active ally of Austria. The crown prince was given the command over the army; no attempt was made to defend Saxony, but the Saxons fell back into Bohemia and effected a junction with the 1st Austrian army corps under Clam-Gallas. They took a prominent part in the battles by which the Prussians forced the line of the Iser and in the disastrous battle of Gitschin. The crown prince, however, succeeded in effecting the retreat in good order, and in the decisive battle of Königgrätz he held the extreme left of the Austrian position. The Saxons maintained their post with great tenacity, but were driven back after many hours' fighting. During these operations the crown prince won the reputation of a thorough soldier; after peace was made and Saxony had entered the North German Confederation, he was placed in command of the Saxon army, which had now become the 12th army corps of the North German army, and in this position carried out the necessary reorganization. He was a firm adherent of the Prussian alliance. On the outbreak of war in 1870 he again commanded the Saxons, who were included in the 2nd army under Prince Frederick Charles, his old opponent. At the battle of Gravelotte they formed the extreme left of the German army, and with the Prussian guard carried out the attack on St Privat, the final and decisive action in the battle. In the reorganization of the army which accompanied the march towards Paris the crown prince was given a separate command over the 4th or army of the Meuse, consisting of the Saxons, the guards, and the 4th army corps; he was succeeded in his former post by his brother Prince George, who had served under him in Bohemia. He took a leading part in the operations which preceded the battle of Sedan, the 4th army being the pivot on which the whole army wheeled round in pursuit of MacMahon; and the actions of Busancy and Beaumont on 29th and 30th August were fought under his directions; in the battle of Sedan itself, with the troops under his orders, he carried out the circumvention of the French on the east and north. His conduct in these engagements won for him the complete confidence of the army, and during the siege of Paris his troops formed the north-east section of the investing force. After the conclusion of the armistice he was left in command of the German army of occupation, a position which he held till the fall of the Commune. On the conclusion of peace he was made an inspector-general of the army and field-marshal. On the death of his father on 29th October 1873 he succeeded to the throne. His reign has been uneventful, and he has taken little public part in political affairs, but his advice and experience have been constantly used in military matters. In 1897 he was appointed arbitrator between the claimants for the principality of Lippe. King Albert married in 1853 Carola, daughter of Prince

Gustavus of Vasa, and grand-daughter of the last king of Sweden of the house of Holstein. (J. W. HE.)

Albert Nyanza AND **Albert Edward Nyanza**, the two western reservoirs of the White Nile, lying north and south in the great Central African rift-valley, near its north end. When the northern lake, Albert Nyanza, was first reached by Sir Samuel Baker, it was thought to extend southwards far beyond the equator—farther, in fact, than the southern end of Albert Edward Lake, which does not reach to 1° S. In 1875 Stanley reached the arm of a lake, situated on the equator, which he thought to be Albert Nyanza, but which the voyages of Gessi and Mason on the latter lake in 1876 and 1877 proved to be distinct.

The true position and form of Albert Edward Nyanza were made known by Stanley's journey of 1888-89, while its contours have since been determined with greater exactness by Stuhlmann (1891) and Grogan and Moore (1899). The lake, which lies at an altitude of about 3200 feet, is roughly elliptical in outline, with a length of 50 miles and maximum breadth of about 30 miles, the area approximating to 1000 square miles. The arm above alluded to is practically an independent lake (Ruisamba) running to the north-east and connected by a narrow channel with the main lake. A swampy plain, traversed by the Ruchuru and other streams, extends to the south of the lake, and must once have been covered by its waters. On the east a wide space intervenes between the eastern wall of the rift-valley and the present shore of the lake, two distinct terraces being clearly defined. The vegetation (Euphorbias, &c.) on the lower of these is of small size and seems to be of recent origin. Near the lake, pits of fire and huge jets of smoke still testify to the presence of volcanic activity. On the west the wall of the rift-valley runs close to the lake, but on the north a barren level plain comes between the lake and the southern spurs of the Ruwenzori range. On this plain, separated by a narrow neck of land from Lake Albert Edward, is a crater-like depression occupied by a shallow salt lake. The salt, which has a reddish tint, is exported to great distances. The main feeder of Lake Albert Edward, the Ruchuru, rises on the north side of the volcanoes north of Lake Kivu (*q.v.*). On reaching the level plain 15 miles from the lake its waters become brackish, and the vegetation on its banks is scanty. The reedy marshes near its mouth form a retreat for a primitive race of fishermen. Lake Ruisamba, the shores of which are generally high, is fed by streams from the east of Mount Ruwenzori. At the north-west corner of the larger lake issues the Isango or Semliki, at first a small stream, but gradually increased to a large river by streams from the Ruwenzori range on the eastern side of the rift-valley. Before entering Albert Nyanza, in 1° 5' N., it traverses a plain once covered by the latter lake, forming marshes inhabited by another tribe of fishermen, the Wanyabuga. The shores of Lake Albert Edward are partitioned between British East Africa and the Congo Free State, the dividing line being here the 30th meridian of east longitude. Just east of that line the British post of Fort George was established on the north shore by Lugard in 1891.

Lake Albert lies at an altitude of about 2100 feet. Its extreme length is about 100 miles, and its general breadth somewhat over 20, the area being approximately 2000 square miles. It is shut in both on the east and west by plateau escarpments, which for the most part approach the shores closely. Near the south end a plain, saline in places, with a width of some 7 miles, intervenes on the west between the plateau and the lake. At this part there are signs that the lake is shrinking, Nyamsasi, which was an island at the time of Stanley's visit in 1889,

having since become a peninsula. Farther north, from Kahoma to Mahagi, the hills descend abruptly to the water, rocky headlands alternating with semicircular beaches. Near the coast the water is in places very shallow, owing to the sediment brought down by mountain torrents, and reeds have been seen growing 2 miles from the shore. The gorges cut in the plateau escarpment produce magnificent timber. This plateau—a sparsely-inhabited rolling upland 2000 to 3000 feet above the lake (the Blue Mountains of Baker)—falls again steeply on the west to the Congo Basin, its maximum width being about 20 miles. The greater part of the shores of Lake Albert fall to British East Africa (Uganda Protectorate), but the stations established at Kibero on the east and Mswa on the west have been abandoned, owing to their unhealthiness. The extreme north-west portion has been leased to the Congo Free State during King Leopold's lifetime, and of this a strip 15 miles wide, reaching the lake at Mahagi, will eventually revert to the state. (E. HE.)

Alberta. See NORTH-WEST TERRITORIES.

Albertina. See ORANGE RIVER COLONY.

Albi, chief town of department Tarn, France, 423 miles S. of Paris, on railway from Carmaux to Castelnau-dary. The Park of Rohegude, gift of the admiral of that name, contains a fountain adorned with 13th-century carvings. On the Vigan, a fine promenade, is a statue of the navigator La Pérouse, who was born here. Manufactures of umbrellas and hats, the latter forming a considerable branch of industry, have become important. Population (1881), 14,729; (1891), 14,219; (1896), 14,983, (comm.) 18,750.

Albina, formerly a city of Multnomah county, Oregon, U.S.A., annexed to Portland in 1891. It is on the east bank of the Willamette river, not far from its mouth, in the north-western part of the state. The population in 1880 was 123; in 1890 it was 5129; in 1900 (see PORTLAND).

Albox, a town of Spain, in the province of Almeria, 42 miles N.N.E. of Almeria. It owes its prosperity to woollen, spart, and flour industries, and to the wine, olive oil, and spart produced in the surrounding fertile country, where also live stock is abundant, especially sheep, goats, and mules. Population (1897), 10,313. Albox was originally an Arab town, Box. An earthquake almost entirely destroyed it in 1563, and it had to be rebuilt in great part.

Albrecht, Frederick Rudolph, ARCHDUKE OF AUSTRIA (1817-1895), eldest son of the Archduke Charles who defeated Napoleon at Aspern, was born on 3rd August 1817 at Vienna. He began his military career at the age of twenty, and after holding several minor posts, was in 1844 appointed commander of the forces in Upper and Lower Austria. It was his duty therefore to maintain order during the disturbances of 1848, and at the outbreak of revolution in Vienna during the month of March he was in command of the troops who came into collision with the rioters. Owing to the collapse of the Government it was impossible to repress the disturbances, and he was relieved from a post which brought much unpopularity and was not suitable to be held by a member of the imperial family. Like so many others of the Austrian military he spent the summer of 1848 in the army of Italy, under Radetzky, and though he was given no command he fought with distinction as a volunteer in the battles of Santa Lucia and Pastrengo. In the campaign of 1849 he was placed in command of the second division, which was in the vanguard of the army, and he gained

great credit for the resolution with which, at the battle of Novara, he held his ground against the superior forces of the enemy. From 1851 to 1860 he commanded the forces in Hungary, a post of great political difficulty. In 1859 and 1864 he was sent on important military and diplomatic missions to Berlin. When war became imminent in 1866 the archduke, who had now been made field-marshal, was placed in command of the Austrian army in Italy. With an army of about 130,000 he had to keep in check the Italian forces of nearly double the number. In the short campaign which followed he displayed the highest military qualities; leaving only a small force to watch the army which was advancing from the Po, with 75,000 men he attacked 130,000 Italians, who under the command of the king had crossed the Mincio, and at the battle of Custozza (23rd June) defeated them with the loss of 8000 men and fourteen cannon. The result of this battle was that both the Italian armies had to retreat, and the archduke was able to send 50,000 men to reinforce the northern army, when, after being defeated by the Prussians, it fell back on Vienna. The Italians, moreover, had to give up the hope of obtaining from Austria any territory except Venetia. On 10th July the archduke was summoned to Vienna to take command of the combined forces which were being collected to defend the capital, but peace was made before further hostilities took place. From this time he was chiefly occupied with the reform and reorganization of the Austrian army; he was made inspector-general of the forces in 1868. In 1870 he conducted the military negotiations preparatory to an alliance with France, which, however, was not concluded. He married, in 1844, Hildegard, daughter of Ludwig, first king of Bavaria, who died in 1864. He died himself 18th February 1895, leaving two daughters. His only son died in childhood, and his nephew, Archduke Frederick (born 1856), inherited his great possessions.

(J. W. H.E.)

Albuquerque, a city of New Mexico, U.S.A., the capital of Bernalillo county, situated in the central part of the territory, on the east bank of the Rio Grande, in 35° 05' N. lat. and 106° 38' W. long., at an altitude of 4950 feet. The streets extend in a regular plan over a plain sloping gently to the river. It is the connecting point of two main lines of the Atchison, Topeka, and Santa Fe railway system. The old Mexican town of Albuquerque, which antedates American jurisdiction over the region, lies about two miles north-west of the modern town, with which it is connected by a street railway. The population of the new town in 1890 was 3785, and in 1900 it was 6238; of the old Mexican town, 1733 in 1890, and 1191 in 1900.

Albury, a town in Australia, New South Wales, in the county of Goulburn; it stands on the border of Victoria and on the right bank of the Murray river, here spanned by two bridges, one carrying the roadway, the other the double railway; 386 miles by rail from Sydney. The Murray is navigable for small steamers from this town to its mouth, a distance of 1800 miles. Altitude 572 feet. Mean rainfall (23 years) 26.39 inches. Population (1881), 5715; (1891), 5447; (1901), 5820.

Alcala de Henares, a city of Spain, 17 miles E.N.E. of Madrid. Population, 8745. After the transfer of the university to Madrid the Government turned most of the principal buildings erected by Cardinal Cisneros in the 16th century into a dépôt for the archives of various state departments. Here, too, are kept very complete and curious documents of the Inquisition, showing all its workings from the 15th to the 19th century.

Alcala de los Cazules, a town of Spain, province of Cadiz, 32 miles E. by S. of Cadiz. It has a splendid climate, and the soil in the surrounding districts is very fertile. There is a prosperous cork industry. It was originally a Moorish town, as its name indicates. Population (1897), 10,027.

Alcamo, a town of Sicily, Italy, in the province of Trapani, 24 miles S.W. from Palermo. It stands 837 feet above sea-level, and produces wine. It was originally a Saracenic town, and was made Christian by the Emperor Frederick II. in 1233. Population (1881), 37,697; (1901), 51,811.

Alcester, a market-town and railway station, under a rural district council, in the south-western parliamentary division of Warwickshire, England, on the Alne, 15 miles W.S.W. of Warwick. A Roman Catholic school chapel, a hospital for infectious diseases, and a reading room have been erected. The manufacture of needles has declined; in the town there are implement works, cycle works, and a brewery. Area, 1626 acres. Population of rural district (1901), 11,392.

Alcester, Frederick Beauchamp Paget Seymour, BARON (1821-1895), British admiral, son of Colonel Sir Horace Beauchamp Seymour, and cousin of Francis George Hugh Seymour, 5th Marquis of Hertford, was born on 12th April 1821. Entering the navy in 1834, he served in the Mediterranean and the Pacific, was for three years flag-lieutenant to his uncle Sir George Seymour, and was promoted to be commander in 1847. He served in Burma as a volunteer in 1852; was made a captain in 1854; took the *Meteor* ironclad battery out to the Black Sea and home again in 1856; was captain of the *Pelorus* on the Australian station from 1857 to 1863, and commanded the naval brigade in New Zealand during the Maori war, 1860-61, for which he was made a C.B. He became a rear-admiral in 1870; in 1871-72 he commanded the flying squadron; was a lord of the Admiralty in 1872-74, and commanded the Channel fleet, 1874-76. On 31st December 1876 he was made a vice-admiral; a K.C.B. on 2nd June 1877. In 1880-83 he was commander-in-chief of the fleet in the Mediterranean, and in 1880 had also the chief command of the European squadron sent to the coast of Albania as a demonstration to compel the Porte to cede Dulcigno to Montenegro. On 24th May 1881 he was made a G.C.B., and on 6th May 1882 was promoted to the rank of admiral. In July 1882 he commanded at the bombardment of Alexandria and in the subsequent operations on the coast of Egypt, for which service he was raised to the peerage as Baron Alcester of Alcester in the county of Warwick, received a parliamentary grant of £25,000, the freedom of the city of London, and a sword of honour. On his return from the Mediterranean he was for a couple of years again at the Admiralty, and in 1886 he was placed on the retired list. For the next nine years he lived chiefly in London, but latterly his health was much broken, and he died on 30th March 1895. He was unmarried, and the peerage became extinct.

(J. K. L.)

Alcock, Sir Rutherford (1809-1897), British consul and diplomatist, was the son of Dr Thomas Alcock, who practised at Ealing, near London, and himself followed the medical profession. In 1836 he became a surgeon in the marine brigade which took part in the Carlist war, and gaining distinction by his services was made deputy inspector-general of hospitals. He retired from this service in 1837, and seven years later was appointed consul at Foochow in China, where, after a short official stay at Amoy, he performed the functions, as he himself expressed

it, "of everything from a lord chancellor to a sheriff's officer." Foochow was one of the ports opened to trade by the treaty of 1842, and Mr Alcock, as he then was, had to maintain an entirely new position with the Chinese authorities. In so doing he was eminently successful, and earned for himself promotion to the consulate at Shanghai. Thither he went in 1846, and made it an especial part of his duties to superintend the establishment and laying out of the British settlement, which has developed into such an important feature of British commercial life in China. In 1858 he was appointed consul-general in the newly-opened empire of Japan, and in the following year was promoted to be minister plenipotentiary. In those days residence in Japan was surrounded with many dangers, and the people were intensely hostile to foreigners. In 1860 Mr Alcock's native interpreter was murdered at the gate of the Legation, and in the following year the Legation was stormed by a body of Ronins, whose attack was repulsed by Mr Alcock and his staff. Shortly after this event he returned to England on leave. Already he had been made a C.B. (1860), and in 1862 he was made a knight commander of the order. Two years later he returned to Japan, and after a year's further residence he was transferred to Peking, where he represented the British Government until 1871, when he retired. But though no longer in official life his leisure was fully occupied. He was for some years president of the Royal Geographical Society, and he served on many commissions. He was twice married, first in May 1841 to Henrietta Mary, daughter of Charles Bacon, Esq., who died in 1853, and secondly (8th July 1862) to the widow of the Rev. John Lowder, who died on 13th March 1899. He was the author of several works, but the one by which he will be known is *The Capital of the Tycoon*, which appeared in 1863. He died in London on 2nd November 1897.

(R. K. D.)

Alcott, Amos Bronson (1799-1888), American educationalist and writer, was born in Wolcott, Connecticut, 29th November 1799. His father was a farmer and mechanic, Joseph Chatfield Alcox, whose ancestors, then bearing the name of Alcocke, had settled in eastern Massachusetts in early colonial days. The external events in Amos Bronson Alcott's long life were for the most part, simple and unimportant. Self-educated in youth, and early thrown upon his own resources, he began to earn his living by peddling books and merchandise in Virginia, afterward teaching in that state and in other southern states. Determined to devote himself to educational work, in 1828 he opened, in Boston, a school which became locally famous because of his original methods; his plan being to develop self-instruction on the basis of self-analysis, with an ever-present desire on his own part to stimulate the child's personality. The feature of his school which attracted most attention, perhaps, was his scheme for the teacher receiving punishment, in certain circumstances, at the hands of an offending pupil, whereby the sense of shame might be quickened in the mind of the errant child. The school was not pecuniarily successful, although Alcott had won the affection of some of his pupils, and his educational experiments had challenged the attention of students of pedagogy. After a visit to England, in 1842, he founded, with two English associates, at "Fruitlands," in the town of Harvard, Massachusetts, a communistic experiment at farm-living and nature-meditation, as tending to develop the best powers of body and soul. This speedily came to naught, and Alcott subsequently took up his home near Emerson, in Concord, Massachusetts, and spoke, as opportunity offered, before the "lyceums" then common in various

parts of the United States, or addressed groups of hearers as they invited him. These "conversations" as he called them, were more or less informal talks on a great range of topics, spiritual, æsthetic, and practical, in which he emphasized the ideas of the school of American Transcendentalists led by Emerson, who was always his supporter and discreet admirer. He dwelt upon the illumination of the mind and soul by direct communion with the Creative Spirit; upon the spiritual and poetic monitions of external nature; and upon the benefit to man of a serene mood and a simple way of life. As regards the trend and results of Alcott's philosophic teaching, it must be said that, like Emerson, he was sometimes inconsistent, hazy, or abrupt. But though he formulated no system of philosophy, and seemed to show the influence now of Plato, now of Kant, or of German thought as filtered through the brain of Coleridge, he was, like his American master, associate, and friend, steadily optimistic, idealistic, individualistic. The teachings of William Ellery Channing, a little before, as to the sacred inviolability of the human conscience—anticipating the later conclusions of Martineau—really lay at the basis of the work of most of the Concord Transcendentalists and contributors to *The Dial*, of whom Alcott was one. In his last years, living in a serene and beautiful old age in his Concord home, where every comfort was provided by his daughter Louisa (*q.v.*), Alcott was gratified at being able to become the nominal, and at times the actual, head of a Concord summer school of philosophy, in which—in a rudely-fashioned building next his house—thoughtful listeners were addressed, during a part of several successive summer seasons, on many themes in philosophy, religion, and letters. Of Alcott's published works the most important is *Tablets* (1868); next in order of merit is *Concord Days* (1872). His *Sonnets and Canzonets*, 1882, are chiefly interesting as an old man's experiments in verse. He left a great and symmetrical collection of personal jottings and memorabilia, most of which remain unpublished. He died in Boston, 4th March 1888.

(C. F. E.)

Alcott, Louisa May (1832-1888), during the last quarter of the 19th century the favourite American author of juvenile stories (especially for girls), was the daughter of Amos Bronson Alcott, and though of New England parentage and residence, was born in Germantown, Pennsylvania, 29th November 1832. She began work at an early age as teacher and writer, and was an amateur nurse in army hospitals during the civil war of 1861-65. Her newspaper letters, collected as *Hospital Sketches* (1863), displayed some power of observation and record; while *Moods*, a novel (1864), despite its uncertainty of method and of touch, indicated the possibility that Miss Alcott might develop into a strong novelist of character, with a sympathetic insight into the deeper springs of vital action. She soon turned, however, to the rapid production of stories for girls, and, with the exception of the cheery tale entitled *Work* (1873), and the anonymous novelette *A Modern Mephistopheles* (1877), which attracted little notice, she did not return to the more ambitious fields of the novelist. Her success dated from the appearance of the first series of *Little Women: or, Meg, Jo, Beth, and Amy* (1868), in which, with unflinching humour, freshness, and lifelikeness, she put into story form many of the sayings and doings of herself and her sisters. *Little Men* (1871) similarly treated the character and ways of her nephews, in that house in Concord, Massachusetts, in which Miss Alcott's industry had now established her parents and other members of the Alcott family; but most of her later volumes,

An Old Fashioned Girl, *Aunt Jo's Scrap Bag* (6 volumes), *Rose in Bloom*, &c., followed in the line of *Little Women*, of which the author's large and loyal public never wearied. Her natural love of labour, her wide-reaching generosity, her quick perception, and her fondness for sharing with her many readers that cheery humour which radiated from her personality and her books, led her to produce stories of a diminishing value, and at length she succumbed to overwork, dying in Boston 6th March 1888, two days after the death of her father in the same city. Miss Alcott's early education had partly been given by the naturalist Thoreau, but had chiefly been in the hands of her father; and in her girlhood and early womanhood she had fully shared the trials and poverty incident to the life of a peripatetic idealist. In a newspaper sketch entitled "Transcendental Wild Oats," afterwards reprinted in the volume *Silver Pitchers*, she narrated, with a delicate humour, which shows what her literary powers might have been if freed from drudgery, the experiences of her family during an experiment towards communistic "plain living and high thinking" in the town of Harvard, Massachusetts, in 1843. The story of her career has been fully and frankly told in Mrs Ednah D. Cheney's *Louisa May Alcott: her Life, Letters, and Journals* (1889), one of the most noteworthy of American biographies, considered as an unconsciously pathetic record of a cheery woman's life-sacrifice for the support and comfort of her relatives. (C. F. R.)

Alcoy, a town of the province of Alicante, Spain. It has much grown in importance owing to its manufactures, in which that of linen must be included. New private and public schools, a chamber of commerce, town hall, barracks, hospital, institute, and casinos have been built and the churches repaired. It has been frequently the scene of strikes and popular disturbances. Population (1897), 30,118.

Alcyonaria. See ANTHOZOA.

Aldan, a river of Asiatic Russia, East Siberia, a right bank tributary of the Lena, rises in the southern parts of the high plateau of East Siberia, flows mostly over desert highlands for 1160 miles N.E., N., and N.W., and joins the Lena 120 miles below Yakutsk. There are a few settlements in its lower course. The *Aldan Range* is the name given to the part of the Stanovoi border range which faces the Sea of Okhotsk.

Aldeburgh, or ALDBOROUGH, a municipal borough (1885), market-town, and railway station in the Woodbridge parliamentary division of Suffolk, England, on the coast, 24 miles E.N.E. of Ipswich. A small 16th-century moot-hall, restored in 1855, is used for corporation meetings. The church of St Peter and St Paul was restored in 1882 and 1891. A jubilee hall has been erected. There is an excellent golf course. Area, 1972 acres. Population (1881), 2106; (1891), 2159; (1901), 2405.

Aldershot, a town and parish of England, 35 miles S.W. of London by rail, in the Basingstoke parliamentary division of Hampshire, situated one mile from the Basingstoke Canal. A mere village till 1855, when Aldershot Camp was established, the town was in 1857 erected into a local government district, and in 1894 was created an urban district. The ancient parish church was restored in 1891. There are a theatre and a cottage hospital (1897). Area of urban district, 4178 acres. Population (1881), 20,155; (1891), 25,595; (1901), 30,974.

Military Depot.—"Camp" is no longer a suitable name for the military buildings at Aldershot. The wooden huts erected in 1855, which formed the North and South Camps, were not calculated to last many years, and it became necessary to replace them with permanent buildings. A commencement was made in 1881, and under

the Barracks Act, 1890, and the Military Works Acts of 1897 and 1899, large sums were provided for completing the work. Although a few wooden buildings remain for a time, the expenditure of nearly £1,800,000 thus provided has made Aldershot, at the commencement of the 20th century, by far the largest assemblage of permanent barracks, as well as the greatest training station for troops, in the British Empire.

The Old North Camp is now named Marlborough Lines, with a three-battery field artillery barrack and five infantry battalion barracks called after Marlborough's victories—Blenheim, Malplaquet, Oudenarde, Ramillies, and Tournay. South Camp is now named Stanhope Lines, after Mr Stanhope, secretary of state for war when the Barracks Act, 1890, was passed and the reconstruction commenced in earnest. They contain barracks for the Royal Engineers and Army Service Corps north of the General Parade, which stretches east and west, and four infantry battalion barracks south of it, with a fifth at the east, called Albuera, Barossa, Corunna, Maida (Sicily), and Mandora (Egypt), after battles of the wars with France, 1793-1815, in which Wellington did not command. There are also barracks for the Royal Army Medical Corps. The old permanent barracks have been renamed Wellington Lines, with barracks for three cavalry regiments, west, east, and south; for three batteries of horse and three batteries of field artillery; and for three infantry battalions called Badajos, Salamanca, and Talavera, after Wellington's victories in the Peninsula. For the sick there are the Connaught Hospital in Marlborough Lines, the Cambridge Hospital in Stanhope Lines, and the Union Hospital in Wellington Lines, besides the Louise Margaret Hospital for women and children alongside Cambridge Hospital, and the infection hospital on the isolated Thornhill, half for men and half for women and children. The buildings in Wellington Lines, for the most part completed about 1857, are in some respects not up to the modern standard, but those in Stanhope and Marlborough Lines may be regarded as typical examples of modern barracks and hospitals.

The drainage of the station is all modern and of the best description, and the sewage is disposed of on a sewage farm worked by an expert, under the direction of the War Department, with the primary object of meeting all sanitary requirements, not of making a profit. The water-supply is partly from the Aldershot Water Company, and partly from springs and reservoirs collecting water from a reserved area of War Department property. The lighting of Wellington Lines is by gas, and Stanhope and Marlborough Lines are lighted by electricity.

Most of the barracks are large enough to accommodate not only the units they are constructed for, but also detachments of soldiers from other stations who are going through courses of instruction. Including these detachments and the large number of soldiers' wives and children for whom quarters are provided, the population of the station may at times reach a total of 24,000, with 4000 or more horses.

Besides the regimental buildings there are a large number of buildings for garrison purposes, in addition to the hospitals already mentioned; such as quarters and offices for general, staff, and departmental officers, with the warrant and non-commissioned officers employed under them; the supply depot with abattoir and bakery, whence the garrison is supplied with rations both of food and forage; the ordnance stores, where are kept all kinds of military stores and mobilization equipment, barrack stores for furniture and bedding, engineer shops and stores for services performed by the Royal Engineers, the balloon establishment for the manufacture of military balloons, the vaccine establishment for the production of calf-lymph for the army, the military prison, fire brigade stations, five churches, recreation grounds for officers and men, schools for the literary instruction of adults and children, and especially those military technical schools which form one of the chief features of Aldershot as a training station. These technical schools are as follows: army cookery school, for training cooks who shall not only cook for soldiers, but also teach them to cook for themselves; army gymnastic school, for the gymnastic instruction of the troops at Aldershot, and especially for training instructors for other stations; Army Service Corps school, for instruction of Army Service Corps officers in their duties; army signalling school, for training signallers; army veterinary school, for training of officers and men, the latter as farriers; ballooning school, for instruction and training of officers and men in the management of balloons; mounted infantry school, for instruction of officers and men in the duties of mounted infantry, the whole training of which force is carried out at Aldershot; training school for Royal Army Medical Corps, for training officers and men for their duties in hospital and field.

The work of these schools is, however, only a small part of the

military training afforded at Aldershot: there still remain those very important branches for which Aldershot was originally started, and for the carrying out of which a considerable extent of land is essential, viz., musketry, company training, reconnaissance, and field days. For these purposes a large tract of land was purchased between 1854 and 1860, and since then additional property has been acquired from time to time, so that at present it extends, though with many interruptions, over an area about 9½ miles in extreme length by 7½ miles in extreme width. In addition to this there is the land at Sandhurst and the Staff College, about 6½ miles distant, and at Wolmer Forest, 12 miles distant. The musketry practice of the troops at Aldershot is carried out at the Ash ranges, 2 miles east of the barracks, while the Pirbright ranges, alongside those of the National Rifle Association at Bisley, are utilized by the household cavalry and guards, who are encamped there in succession. Suitable land, within an easy march of the barracks, is utilized for company, battalion, and brigade training of infantry, while the mounted branches work over a wider area, and the engineers carry out their practices where most convenient. For field days of the three arms—cavalry, artillery, and infantry—the whole of the War Department property is available.

Besides the troops in barracks, during the drill season there is often a considerable force in camp, both regular troops from other stations, and militia and volunteers. Some sixty camping grounds have been specially prepared for them, so that, including the regular garrison, sometimes as many as 40,000 troops have been concentrated at the station for training and manoeuvres.

(H. LO.)

Aldrich, Thomas Bailey (1836—), American author, was born in Portsmouth, New Hampshire, on the 11th November 1836; his birthplace being the "Rivermouth" of several of his longer and shorter stories, while the Piscataqua river, the Isles of Shoals, and other scenes familiar to his boyhood, are frequently commemorated in his prose and verse. His early life—partly described in his *Story of a Bad Boy* (1869), in which "Tom Bailey" is the juvenile hero—was spent in business offices in New Orleans and New York, until his literary tastes led him to become a contributor to various newspapers in the latter city. Between 1856 and 1859 he was on the staff of the *New York Home Journal*, then edited by the once popular poet N. P. Willis; while during a part of the Civil war he was editor-in-chief of the *New York Illustrated News*, the most graphic of the pictorial recorders of that conflict. These journalistic experiences brought him into close relations with Stedman, Stoddard, Taylor, Whitman, the sculptor Launt Thompson, and many others of the younger writers and artists of the "sixties," some of whom essayed to set up a mild Bohemia in the American metropolis. In later years he edited the eclectic (and, for a time, illustrated) weekly *Every Saturday*, Boston, between 1870 and 1874, and *The Atlantic Monthly* for nine years, beginning with 1881. Aldrich's successive books of verse, chiefly *The Ballad of Babie Bell* (1856), *Pampinea*, and *Other Poems* (1861), *Flower and Thorn* (1876), *Friar Jerome's Beautiful Book* (1881), *Thirty-six Lyrics and Twelve Sonnets* (1881), *Mercedes and Later Lyrics* (1883), *Wyndham Towers* (1889), and the collected editions of 1865 and 1882, showed him to be a poet of lyrical skill, dainty touch, and felicitous conceit, the influence of Herriek being constantly apparent. He has repeatedly essayed the long narrative or dramatic poem, but seldom with success, save in such earlier work as *Garnaut Hall* in the 1865 collection. But no American poet has shown more skill in describing some single picture, mood, conceit, or episode. The best things he has written are such lyrics as "Hesperides," "When the Sultan goes to Ispahan," "Before the Rain," "Nameless Pain," "The Tragedy," "Seadrift," "Tiger-Lilies," "The One White Rose," "Palabras Cariñosas," "Destiny," or the eight-line poem "Identity," which did more to spread Aldrich's reputation than any of his writing after the "Babie Bell" of 1856. Beginning with the collection of stories entitled *Marjorie Daw and Other People* (1873),

Aldrich applied to his later prose work that minute care in composition which had previously characterized his verse—taking a neat, new, or salient situation, and setting it before the reader in a pretty combination of kindly realism and reticent humour. In the novels of *Prudence Palfrey* (1874), *The Queen of Sheba* (1877), and *The Still-water Tragedy* (1880), there is more rapid action; but the Portsmouth pictures in the first-named are elaborated with the affectionate touch shown in the shorter humorous tale, *A Rivermouth Romance*. In *An Old Town by the Sea* (1893) the author's birthplace was once more commemorated in plainer colours, while travel and description are the theme of the chapters entitled *From Ponkapog to Pesth* (1883), though the portrayals are still those of a poet and humorist.

Aleardi, Aleardo, COUNT (1812-1878), Italian poet, was born at Verona, 4th November 1812, and thus soon after his birth became an Austrian subject. Inspired from his cradle with a hatred of the foreigner, he found himself disqualified for the position in the public service to which his rank would have entitled him, and unable to publish his patriotic verses. *Arnaldo da Rocca*, a narrative poem, nevertheless appeared in 1842, and the revolutionary year 1848 made an opening for his *Lettere a Maria*. He took an active part in the popular uprising, and was for some time imprisoned. In 1856 he produced the finest of his pieces, an ode to the maritime cities of Italy, and in 1858 a poem on his own misfortunes. After the expulsion of the Austrians from Lombardy he returned to Verona, published his poems in a collected edition, became professor at the Academy of Fine Art, member of the Italian Parliament, and eventually senator. He died on 17th July 1878. Aleardi's warmth of patriotic feeling hardly finds adequate expression in his poetry; it is his merit to excel in description, but his fault to substitute description for action.

Alefi. See NEW CALEDONIA.

Alemtejo, a southern province of Portugal, measuring 155 miles long from N. to S., and 60 miles in mean breadth, with an area of 9425 square miles, and population 393,054; density, 41.7 inhabitants to the square mile. The horses in this province embrace the Alter breed, the finest in the kingdom. Marble is found, and there are copper and iron mines. Mineral waters exist at Aljustrel, Cabeço de Vide, Mertola, Ouguella, Portalegre, Souzel, and Vimieiro. Cloth is manufactured at Portalegre and pottery at Estremoz. The only port is Villa Nova de Milfontes. There are meteorological stations at Evora, Beja, and Campo Maior.

Aleppo, (1) a vilâyet of Asiatic Turkey, in Northern Syria. The mountain districts, which occupy nearly half the area, are rich in mineral wealth, and the large inland plains are fertile but uncultivated. Mineral springs are numerous. Nearly all the external trade passes through Alexandretta; the average annual value of the exports for 1896-98 was £1,075,453, and of imports £2,014,012. Population, 995,800 (Moslems and Ansarieh, 792,400; Christians, 183,400; Jews, 20,000). (2) The chief town of the vilâyet, situated near the edge of the Syrian desert, in a fertile valley, almost enclosed by limestone hills, through which runs the Koweik (*Chalus*). Its former importance and rapid recovery from repeated disaster were due to its position on the caravan route to Baghdad, Persia, and India. Its large trade led to the establishment of a British consulate and factory in the reign of Elizabeth. The opening of the sea route to India affected its prosperity, but it is still the emporium of Northern Syria, and connected with its port Alexandretta by a carriage road (96

miles). Aleppo was a place of importance 2000 years B.C., and is mentioned in Egyptian and Assyrian inscriptions. It was enlarged and called *Berea* by Seleucus Nicator, but the old name afterwards reasserted itself under the form *Haleb*. It was rebuilt after an earthquake in the 12th century by the famous Núr ed-Dín, and was closely connected with the history of Saladin and his successors. The town has always retained its Arab character, and the Christians and Jews have their own quarters. Population, 129,000 (Moslems, 98,000; Christians, 23,000; Jews, 8000). It is the seat of a British consulate.

Alessandria, chief town of the Italian province of the same name, situated almost entirely upon the right bank of the river Tanaro, slightly to the west of its confluence with the Bormida. It is distant 57 miles from Turin by rail. The population numbers 70,000, half living in the city proper and half in the suburbs. Alessandria is therefore divided into two municipal districts, the one within, the other outside the walls. It is the headquarters of the second army corps. From a military point of view its importance is great, its citadel being considered one of the principal bulwarks of Italy and the strategic key of Piedmont. The interior of the cathedral was recently restored in Bramantesque style, according to designs by Count Mella. Among public buildings are the provincial and municipal palaces, the civil hospital, lately remodelled in accordance with modern hygienic exigencies, the synagogue, the lunatic asylum, the episcopal seminary, the library, and the municipal theatre. The cattle market with its vast roofing and pens is the most important in Italy. Education is provided for by a royal lyceum-gymnasium, by a technical school and an institute, and by a normal female school. In regard to charitable institutions Alessandria is provided with a foundling hospital, a refuge for mendicants, and several asylums and hospitals. More than 50 mutual benefit associations provide for the insurance of the working classes, while an important savings bank testifies to the thrift of the population. The principal monuments are statues to the liberal statesman Urbano Rattazzi, to Andrea Vochieri, and to the Alessandrians who fell during the Risorgimento. The chief manufactures are furniture-making, hat-making, and iron-smelting. Trade is favoured by the circumstance that the town stands at the converging point of several valleys, rich both in industrial and agricultural products. (A. FE.)

Aleutian Islands. See ALASKA.

Alexander II. (1818-1881), emperor of Russia, eldest son of Nicholas I., was born on 29th April 1818. His early life gave little indication of his subsequent activity, and up to the moment of his accession in 1855 no one ever imagined that he would be known to posterity as a great reformer. In so far as he had any decided political convictions, he seemed to be animated with that reactionary spirit which was predominant in Europe at the time of his birth, and continued in Russia to the end of his father's reign. In the period of thirty years during which he was heir-apparent, the moral atmosphere of St Petersburg was very unfavourable to the development of any originality of thought or character. It was a time of government on martinet principles, under which all freedom of thought and all private initiative were as far as possible suppressed vigorously by the administration. Political topics were studiously avoided, in general conversation, and books or newspapers in which the most keen-scented press-censor could detect the least odour of political or religious free-thinking were strictly prohibited. Criticism of existing authorities was regarded as a serious offence. The common policeman, the insignificant scribe in a public office, and even the actors in the "imperial" theatres, were protected

against public censure as effectually as the Government itself; for the whole administration was considered as one and indivisible, and an attack on the humblest representative of the imperial authority was looked on as an indirect attack on the fountain from which that authority flowed. Such was the moral atmosphere in which young Alexander Nicolaevitch grew up to manhood. He received the education commonly given to young Russians of good family at that time—a smattering of a great many subjects, and a good practical acquaintance with the chief modern European languages. Like so many of his countrymen he displayed great linguistic ability, and his quick ear caught up even peculiarities of dialect. His ordinary life was that of an officer of the Guards, modified by the ceremonial duties incumbent on him as heir to the throne. Nominally he held the post of director of the military schools, but he took little personal interest in military affairs. To the disappointment of his father, in whom the military instinct was ever predominant, he showed no love of soldiering,

ALEXANDER II.

(From a photograph by W. & D. Downey, London.)

and gave evidence of a kindness of disposition and a tender-heartedness which were considered out of place in one destined to become a military autocrat. These tendencies had been fostered by his tutor Zhukovski, the amiable, humanitarian poet, who had made the Russian public acquainted with the literature of the German romantic school, and they remained with him all through life, though they did not prevent him from being severe in his official position when he believed severity to be necessary. In 1841 he married the daughter of the Grand Duke Ludwig II. of Hesse, Maximilienne Wilhelmine Marie, thenceforward known as Maria Alexandrovna, who bore him six sons and two daughters. He did not travel much abroad, for his father, in his desire to exclude from Holy Russia the subversive ideas current in Western Europe, disapproved foreign tours, and could not consistently encourage in his own family what he tried to prevent among the rest of his subjects. In the years, however, immediately preceding his accession, he was entrusted with several missions to the courts of Berlin and Vienna. On 2nd March 1855, during the Crimean war, he succeeded to the throne on the death of his father.

The first year of the new reign was devoted to the prosecution of the war, and, after the fall of Sebastopol, to negotiations for peace. Then began a period of radical reforms, recommended by public opinion and carried out by the autocratic power. The rule of Nicholas, which had sacrificed all other interests to that of making Russia an irresistibly strong military power, had been tried by the Crimean war and found wanting. A new system must, therefore, be adopted. All who had any pretensions to enlightenment declared loudly that the country had been exhausted and humiliated by the war, and that the only way of restoring it to its proper position in Europe was to develop its natural resources and to reform thoroughly all branches of the administration. The Government found, therefore, in the educated classes a new-born public spirit, anxious to assist it in any work of reform that it might think fit to undertake. Fortunately for Russia the autocratic power was now in the hands of a man who was impressionable enough to be deeply influenced by the spirit of the time, and who had sufficient prudence and practical common-sense to prevent his being carried away by the prevailing excitement into the dangerous region of Utopian dreaming. Unlike some of his predecessors, he had no grand, original schemes of his own to impose by force on unwilling subjects, and no pet crotchets to lead his judgment astray; and he instinctively looked with a suspicious, critical eye on the panaceas which more imaginative and less cautious people recommended. These traits of character, together with the peculiar circumstances in which he was placed, determined the part which he was to play. He moderated, guided, and in great measure realized the reform aspirations of the educated classes. Though he carefully guarded his autocratic rights and privileges, and obstinately resisted all efforts to push him farther than he felt inclined to go, he acted for several years somewhat like a constitutional sovereign of the Continental type. At first he moved so slowly that many of the impatient, would-be reformers began to murmur at the unnecessary delay. In reality not much time was lost. Soon after the conclusion of peace important changes were made in the legislation concerning industry and commerce, and the new freedom thus accorded produced a large number of limited liability companies. At the same time plans were formed for constructing a great network of railways, partly for the purpose of developing the natural resources of the country, and partly for the purpose of increasing its powers of defence and attack. Then it was found that further progress was blocked by a great obstacle, the existence of serfage; and Alexander II. showed that, unlike his father, he meant to grapple boldly with the difficult and dangerous problem. Taking advantage of a petition presented by the Polish landed proprietors of the Lithuanian provinces, praying that their relations with the serfs might be regulated in a more satisfactory way—meaning in a way more satisfactory for the proprietors—he authorized the formation of committees “for ameliorating the condition of the peasants,” and laid down the principles on which the amelioration was to be effected. This was a decided step, and it was followed by one still more significant. Without consulting his ordinary advisers, his Majesty ordered the minister of the interior to send a circular to the provincial governors of European Russia, containing a copy of the instructions forwarded to the governor-general of Lithuania, praising the supposed generous, patriotic intentions of the Lithuanian landed proprietors, and suggesting that perhaps the landed proprietors of other provinces might express a similar desire. The hint was taken, of course, and in all provinces where serfage existed emancipation committees were formed. The deliberations at once raised a host of important, thorny questions. The eman-

icipation was not merely a humanitarian question capable of being solved instantaneously by imperial ukaz. It contained very complicated problems affecting deeply the economic, social, and political future of the nation. Alexander II. had little of the special knowledge required for dealing successfully with such problems, and he had to restrict himself to choosing between the different measures recommended to him. The main point at issue was whether the serfs should become agricultural labourers dependent economically and administratively on the landlords, or should be transformed into a class of independent communal proprietors. The emperor gave his support to the latter project, and the Russian peasantry accordingly acquired rights and privileges such as are enjoyed by no other peasantry in Europe. In the numerous other questions submitted to him he began by consulting carefully the conflicting authorities, and while leaning as a rule rather to the side of those who were known as “Liberals,” he never went so far as they desired, and always sought some middle course by which conflicting interests might be reconciled. On the 3rd of March 1861, the sixth anniversary of his accession, the emancipation law was signed and published. Other reforms followed in quick succession during the next five or six years: army and navy organization, a new judicial administration on the French model, a new penal code and a greatly simplified system of civil and criminal procedure, an elaborate scheme of local self-government for the rural districts and the large towns, with elective assemblies possessing a restricted right of taxation, and a new rural and municipal police under the direction of the minister of the interior. These new institutions were incomparably better than the old ones which they replaced, but they did not work such miracles as inexperienced enthusiasts expected. Comparisons were made, not with the past, but with an ideal state of things which never existed in Russia or elsewhere. Hence arose a general feeling of disappointment, which acted on different natures in different ways. Some of the enthusiasts sank into a sceptical, reactionary frame of mind; while others, with deeper convictions or capable of more lasting excitement, attributed the failure to the fact that only half-measures and compromises had been adopted by the Government. Thus appeared in the educated classes two extreme groups: on the one hand, the discontented Conservatives, who recommended a return to a more severe disciplinarian régime; and on the other, the discontented Radicals, who would have been satisfied with nothing less than the adoption of a thoroughgoing socialistic programme. Between the two extremes stood the discontented Moderates, who indulged freely in grumbling without knowing how the unsatisfactory state of things was to be remedied. For some years the emperor, with his sound common-sense and dislike of exaggeration, held the balance fairly between the two extremes; but long years of uninterrupted labour, anxiety, and disappointment weakened his zeal for reform, and when radicalism assumed more and more the form of secret societies and revolutionary agitation, he felt constrained to adopt severe repressive measures.

The revolutionary agitation was of a very peculiar kind. It was confined to a section of the educated classes, and emanated from the universities and higher technical schools. At the beginning of the reform period there had been much enthusiasm for scientific as opposed to classical education. Russia required, it was said, not classical scholars, but practical, scientific men, capable of developing her natural resources. The Government, in accordance with this view, had encouraged scientific studies until it discovered to its astonishment that there was some

mysterious connexion between natural science and revolutionary tendencies. Many of the young men and women, who were supposed to be qualifying as specialists in the various spheres of industrial and commercial enterprise, were in reality devoting their time to considering how human society in general, and Russian society in particular, could be reconstructed in accordance with the latest physiological, biological, and sociological principles. Some of these young people wished to put their crude notions immediately into practice, and as their desire to make gigantic socialist experiments naturally alarmed the Government, their activity was opposed by the police. Many of them were arrested and imprisoned or exiled to distant provinces, but the revolutionary work was continued with unabated zeal. Thus arose a struggle between the youthful, hot-headed partisans of revolutionary physical science and the zealous official guardians of political order—a struggle which has made the strange term Nihilism a familiar word not only in Russia but also in Western Europe. The movement gradually assumed the form of terrorism, and aimed at the assassination of prominent officials, and even of the emperor himself, and the natural result was that the reactionary tendencies of the Government were strengthened.

In foreign policy Alexander II. showed the same qualities of character as in internal affairs, ever trying prudently to steer a middle course. When he came to the

Foreign policy.

throne, a peace policy was imposed on him by circumstances. The Crimean war was still going on, but as there was no doubt as to the final issue, and the country was showing symptoms of exhaustion, he concluded peace with the Allies as soon as he thought the national honour had been satisfied. Prince Gortchakoff could then declare to Europe, "*La Russie ne boude pas; elle se recueille*"; and for fifteen years he avoided foreign complications, so that the internal strength of the country might be developed, while the national pride and ambition received a certain satisfaction by the expansion of Russian influence and domination in Asia. Twice, indeed, during that period the chancellor ran the risk of provoking war. The first occasion was in 1863, when the Western Powers seemed inclined to interfere in the Polish question, and the Russian chancery declared categorically that no interference would be tolerated. The second occasion was during the Franco-German war of 1870-71, when the Cabinet of St Petersburg boldly declared that it considered itself no longer bound by the Black Sea clause of the Treaty of Paris. On both these occasions hostilities were averted. Not so on the next occasion, when Russia abandoned her attitude of *recueillement*. When the Eastern Question was raised in 1875 by the insurrection of Herzegovina, Alexander II. had no intention or wish to provoke a great European war. No doubt he was waiting for an opportunity of recovering the portion of Bessarabia which had been ceded by the Treaty of Paris, and he perceived in the disturbed state of Eastern Europe a possibility of obtaining the desired rectification of frontier, but he hoped to effect his purpose by diplomatic means in conjunction with Austria. At the same time he was anxious to obtain for the Christians of Turkey some amelioration of their condition, and to give thereby some satisfaction to his own subjects. As autocratic ruler of the nation which had long considered itself the defender of the Eastern Orthodox faith and the protector of the Slav nationalities, he could not remain inactive at such a crisis, and he gradually allowed himself to drift into a position from which he could not retreat without obtaining some tangible result. Supposing that the Porte would yield to diplomatic pressure and menace so far as to make some reasonable concessions, he delivered his famous Moscow speech, in

which he declared that if Europe would not secure a better position for the oppressed Slavs he would act alone. The diplomatic pressure failed, and war became inevitable. During the campaign he displayed the same perseverance and the same moderation that he had shown in the emancipation of the serfs. To those who began to despair of success, and advised him to conclude peace on almost any terms so as to avoid greater disasters, he turned a deaf ear, and brought the campaign to a successful conclusion; but when his more headstrong advisers urged him to insist on terms which would probably have produced a conflict with Great Britain and Austria, he resolved, after some hesitation, to make the requisite concessions. In this resolution he was influenced by the discovery that he could not rely on the expected support of Germany, and the discovery made him waver in his devotion to the German alliance, which had been the main pivot of his foreign policy; but his personal attachment to the Emperor William prevented him from adopting a hostile attitude towards the empire he had helped to create.

The patriotic excitement produced by the war did not weaken the revolutionary agitation. The struggle between the Terrorists and the police authorities became more and more intense, and attempts at assassination became more and more frequent. Alexander II. succumbed by degrees to the mental depression produced originally by the disappointments which he experienced in his home and foreign policy; and in 1880, when he had reigned twenty-five years, he entrusted to Count Loris-Melikof a large share of the executive power. In that year the empress died, and a few weeks afterwards he married secretly a Princess Dolgoruki, with whom he had already entertained intimate relations for some years. Early in 1881, on the advice of Count Loris-Melikof, he determined to try the effect of some moderate liberal reforms on the revolutionary agitation, and for this purpose he caused an ukaz to be prepared creating special commissions, composed of high officials and private personages who should prepare reforms in various branches of the administration. On the very day on which this ukaz was signed—13th March 1881—he fell a victim to a Nihilist plot. When driving in one of the central streets of St Petersburg, near the Winter Palace, he was mortally wounded by the explosion of some small bombs, and died a few hours afterwards.

(D. M. W.)

Alexander III. (1845-1894), emperor of Russia, second son of Alexander II., was born on 10th March 1845. In natural disposition he bore little resemblance to his soft-hearted, liberal-minded father, and still less to his refined, philosophic, sentimental, chivalrous, yet cunning grand-uncle Alexander I., who coveted the title of "the first gentleman of Europe." With high culture, exquisite refinement, and studied elegance he had no sympathy, and never affected to have any. Indeed, he rather gloried in the idea of being of the same rough texture as the great majority of his subjects. His straightforward, abrupt manner savoured sometimes of gruffness, while his direct, unadorned method of expressing himself harmonized well with his rough-hewn, immobile features and somewhat sluggish movements. His education was not fitted to soften these peculiarities. During the first twenty years of his life he had no prospect of succeeding to the throne, because he had an elder brother, Nicholas, who seemed of a fairly robust constitution. Even when this elder brother showed symptoms of delicate health it was believed that his life might be indefinitely prolonged by proper care and attention, and precautions had been taken for the succession by his betrothal with the Princess Dagmar of Denmark. In these circumstances the greatest solicitude was devoted

to the education of Nicholas as cesarevitch, whereas Alexander received only the perfunctory and inadequate training of an ordinary grand duke of that period, which did not go much beyond primary and secondary instruction, practical acquaintance with French, English, and German, and a certain amount of drill. When he became heir-apparent by the death of his elder brother in 1865, he began to study the principles of law and administration under Professor Podêdonostsef, who did not succeed in awakening in his pupil a love of abstract studies or prolonged intellectual exertion, but who influenced the character of his reign by instilling into his mind the belief that zeal for Eastern Orthodoxy ought, as an essential factor of Russian patriotism, to be specially cultivated by every right-minded Tsar. His elder brother when on his deathbed had expressed a wish that his affianced bride, Princess Dagmar of Denmark, should marry his successor, and this wish was realized on 9th November 1866. The union proved a most happy one and remained unclouded to the end. During those years when he was heir-apparent—1865 to 1881—he did not play a prominent

ALEXANDER III.

part in public affairs, but he allowed it to become known that he had certain ideas of his own which did not coincide with the principles of the existing Government. He deprecated what he considered undue foreign influence in general, and German influence in particular, and he longed to see the adoption of genuine national principles in all spheres of official activity, with a view to realizing his ideal of a homogeneous Russia—homogeneous in language, administration, and religion. With such ideas and aspirations he could hardly remain permanently in cordial agreement with his father, who, though a good patriot according to his lights, had strong German sympathies, often used the German language in his private relations, occasionally ridiculed the exaggerations and eccentricities of the Slavophiles, and based his foreign policy on the Prussian alliance. The antagonism first appeared publicly during the Franco-German war, when the Tsar supported the Cabinet of Berlin and the cesarevitch did not conceal his sympathies with the French. It reappeared in an intermittent fashion during the years 1875-79, when the Eastern Question produced so much excitement in all ranks of Russian society. At first the cesarevitch was more Slavophil than the Government, but his phlegmatic nature preserved him from many of the

exaggerations indulged in by others, and any of the prevalent popular illusions he may have imbibed were soon dispelled by personal observation in Bulgaria, where he commanded the left wing of the invading army. The Bulgarians had been represented in St Petersburg and Moscow not only as martyrs but also as saints, and a very little personal experience sufficed to correct the error. Like most of his brother officers he could not feel any very great affection for the "little brothers," as the Bulgarians were then commonly called, and he was constrained to admit that the Turks were by no means so black as they had been painted. He did not, however, scandalize the believers by any public expression of his opinions, and did not indeed make himself conspicuous in any way during the campaign. Never consulted on political questions, he confined himself to his military duties, and fulfilled them in a conscientious and unobtrusive manner. After many mistakes and disappointments, the army reached Constantinople and the treaty of San Stefano was signed, but much that had been obtained by that important document had to be sacrificed at the Congress of Berlin. Prince Bismarck failed to do what was confidently expected of him. In return for the Russian support, which had enabled him to create the German empire, it was thought that he would help Russia to solve the Eastern Question in accordance with her own interests, but to the surprise and indignation of the Cabinet of St Petersburg he confined himself to acting the part of "honest broker" at the Congress, and shortly afterwards he ostentatiously contracted an alliance with Austria for the express purpose of counteracting Russian designs in Eastern Europe. The cesarevitch could point to these results as confirming the views he had expressed during the Franco-German war, and he drew from them the practical conclusion that for Russia the best thing to do was to recover as quickly as possible from her temporary exhaustion and to prepare for future contingencies by a radical scheme of military and naval reorganization. In accordance with this conviction, he suggested that certain reforms should be introduced. During the campaign in Bulgaria he had found by painful experience that grave disorders and gross corruption existed in the military administration, and after his return to St Petersburg he had discovered that similar abuses existed in the naval department. For these abuses, several high-placed personages—among others two of the grand dukes—were believed to be responsible, and he called his father's attention to the subject. His representations were not favourably received. Alexander II. had lost much of the reforming zeal which distinguished the first decade of his reign, and had no longer the energy required to undertake the task suggested to him. The consequence was that the relations between father and son became more strained. The latter must have felt that there would be no important reforms until he himself succeeded to the direction of affairs. That change was much nearer at hand than was commonly supposed. On 13th March 1881, Alexander II. was assassinated by a band of Nihilists, and the autocratic power passed to the hands of his son.

In the last years of his reign, Alexander II. had been much exercised by the spread of Nihilist doctrines, and the increasing number of anarchist conspiracies, and for some time he had hesitated between strengthening the hands of the executive and making concessions to the widespread political aspirations of the educated classes. Finally he decided in favour of the latter course, and on the very day of his death he signed an ukaz, creating a number of consultative commissions which might have been easily transformed into an assembly of notables. Alexander III. determined to adopt the opposite policy. He at once cancelled the ukaz before it was published, and in the

manifesto announcing his accession to the throne he let it be very clearly understood that he had no intention of limiting or weakening the autocratic power which he had inherited from his ancestors. Nor did he afterwards show any inclination to change his mind. All the internal reforms which he initiated were intended to correct what he considered as the too liberal tendencies of the previous reign, so that he left behind him the reputation of a sovereign of the retrograde type. In his opinion Russia was to be saved from anarchical disorders and revolutionary agitation, not by the parliamentary institutions and so-called liberalism of Western Europe, but by the three principles which the elder generation of the Slavophiles systematically recommended—nationality, Eastern Orthodoxy, and autocracy. His political ideal was a nation containing only one nationality, one language, one religion, and one form of administration; and he did his utmost to prepare for the realization of this ideal by imposing the Russian language and Russian schools on his German, Polish, and Finnish subjects, by fostering Eastern Orthodoxy at the expense of other confessions, by persecuting the Jews, and by destroying the remnants of German, Polish, and Swedish institutions in the outlying provinces. In the other provinces he sought to counteract what he considered the excessive liberalism of his father's reign. For this purpose he clipped the feeble wings of the *Zemstvo*, an elective local administration resembling the county and parish councils in England, and placed the autonomous administration of the peasant communes under the supervision of landed proprietors appointed by the Government. At the same time he sought to strengthen and centralize the imperial administration, and to bring it more under his personal control. In foreign affairs he was emphatically a man of peace, but not at all a partisan of the doctrine of peace at any price, and he followed the principle that the best means of averting war is to be well prepared for it. Though indignant at the conduct of Prince Bismarck towards Russia, he avoided an open rupture with Germany, and even revived for a time the Three Emperors' Alliance. It was only in the last years of his reign, when M. Katkoff had acquired a certain influence over him, that he adopted towards the Cabinet of Berlin a more hostile attitude, and even then he confined himself to keeping a large quantity of troops near the German frontier, and establishing cordial relations with France. With regard to Bulgaria he exercised similar self-control. The efforts of Prince Alexander and afterwards of M. Stamboloff to destroy Russian influence in the principality excited his indignation, but he persistently vetoed all proposals to intervene by force of arms. In Central Asian affairs he followed the traditional policy of gradually extending Russian domination without provoking a conflict with Great Britain, and he never allowed the bellicose partisans of a forward policy to get out of hand. As a whole his reign cannot be regarded as one of the eventful periods of Russian history; but it must be admitted that, under his hard, unsympathetic rule, the country made considerable progress. He died at Livadia on 1st November 1894, and was succeeded by his eldest son, Nicholas II.

(D. M. W.)

Alexander of BATTENBERG (1857-1893), first Prince of Bulgaria, was the second son of Prince Alexander of Hesse and the Rhine by hismorganatic marriage with Julia, Countess von Hauke. The title of Battenberg, derived from an ancient residence of the grand-ducal family of Hesse, was conferred, with the prefix *Durchlaucht* or "Serene Highness," on the countess and her descendants in 1858. Prince Alexander, who was born 5th April 1857, was nephew of the Tsar Alexander II,

who had married a sister of Prince Alexander of Hesse; his mother, a daughter of Count Moritz von Hauke, had been lady-in-waiting to the Tsaritsa. In his boyhood and early youth he was frequently at St Petersburg, and he accompanied his uncle, who was much attached to him, during the Bulgarian campaign of 1877. When Bulgaria under the Berlin Treaty was constituted an autonomous principality under the suzerainty of Turkey, the Tsar recommended his nephew to the Bulgarians as a candidate for the newly-created throne, and Prince Alexander was elected prince of Bulgaria by unanimous vote of the Grand Sobranye, 29th April 1879. He was at that time serving as a lieutenant in the Prussian life-guards at Potsdam. Before proceeding to Bulgaria, Prince Alexander paid visits to the Tsar at Livadia, to the courts of the Great Powers, and to the Sultan; he was then conveyed on a Russian warship to Varna, and after taking the oath to the new constitution at Tirmova (8th July 1879) he repaired to Sofia, being everywhere greeted with immense enthusiasm by the people. (For the political history of Prince Alexander's reign, see BULGARIA.) Without any previous training in the art of government, the young prince from the outset found himself confronted with difficulties which would have tried the sagacity of an experienced ruler. On the one hand he was exposed to numberless humiliations on the part of the representatives of official Russia, who made it clear to him that he was expected to play the part of a *roi fainéant*; on the other he was compelled to make terms with the Bulgarian politicians, who, intoxicated with newly-won liberty, prosecuted their quarrels with a crude violence which threatened to subvert his authority and to plunge the nation in anarchy. After attempting to govern under these conditions for nearly two years, the prince, with the consent of the Tsar Alexander III., assumed absolute power (9th May 1881), and a suspension of the ultra-democratic constitution for a period of seven years was voted by a specially convened assembly (13th July). The experiment, however, proved unsuccessful; the Bulgarian Liberal and Radical politicians were infuriated, and the real power fell into the hands of two Russian generals, Soboleff and Kaulbars, who had been specially despatched from St Petersburg. The prince, after vainly endeavouring to obtain the recall of the generals, restored the constitution with the concurrence of all the Bulgarian political parties (18th September 1883). A serious breach with Russia followed, which was widened by the part which the prince subsequently played in encouraging the national aspirations of the Bulgarians. The revolution of Philippopolis (18th September 1885), which brought about the union of Eastern Rumelia with Bulgaria, was carried out with his consent, and he at once assumed the government of the revolted province. In the anxious year which followed, the prince gave evidence of considerable military and diplomatic ability. He rallied the Bulgarian army, now deprived of its Russian officers, to resist the Servian invasion, and after a brilliant victory at Slivnitza (19th November) pursued King Milan into Servian territory as far as Pirot, which he captured (27th November). Although Servia was protected from the consequences of defeat by the intervention of Austria, Prince Alexander's success sealed the union with Eastern Rumelia, and after long negotiations he was nominated governor-general of that province for five years by the Sultan (5th April 1886). This arrangement, however, cost him much of his popularity in Bulgaria, while discontent prevailed among a certain number of his officers, who considered themselves slighted in the distribution of rewards at the close of the campaign. A military conspiracy was formed, and on the night of the 20th August the prince was seized in the palace at Sofia, and com-

pelled to sign his abdication; he was then hurried to the Danube at Rakhovo, transported on his yacht to Reni, and handed over to the Russian authorities, by whom he was allowed to proceed to Lemberg. He soon, however, returned to Bulgaria, owing to the success of the counter-revolution led by Stamboloff, which overthrew the provisional government set up by the Russian party at Sophia. But his position had become untenable, partly owing to an ill-considered telegram which he addressed to the Tsar on his return; partly in consequence of the attitude of Prince Bismarck, who, in conjunction with the Russian and Austrian Governments, forbade him to punish the leaders of the military conspiracy. He therefore issued a manifesto resigning the throne, and left Bulgaria on the 8th September 1886. He now retired into private life. A few years later he married Fräulein Loisinger, an actress, and assumed the style of Count Hartenau (6th February 1889). The last years of his life were spent principally at Gratz, where he held a local command in the Austrian army. Here, after a short illness, he died on the 23rd October 1893. His remains were brought to Sofia, where they received a public funeral, and were eventually deposited in a mausoleum erected in his memory. Prince Alexander possessed much charm and amiability of manner; he was tall, dignified, and strikingly handsome. His capabilities as a soldier have been generally recognized by competent authorities. As a ruler he committed some errors, but his youth and inexperience and the extreme difficulty of his position must be taken into consideration. He was not without aptitude for diplomacy, and his intuitive insight and perception of character sometimes enabled him to outwit the crafty politicians by whom he was surrounded. His principal fault was a want of tenacity and resolution; his tendency to unguarded language undoubtedly increased the number of his enemies.

The literature relating to Prince Alexander's reign is still scanty. See DRANDAR. *Le Prince Alexandre de Battenberg en Bulgarie*. Paris, 1884.—KOCH. *Fürst Alexander von Bulgarien*. Darmstadt, 1887.—MATVEYEV. *Bulgarien nach dem Berliner Congress*. Petersburg, 1887.—BOURCHIER. "Prince Alexander of Battenberg," in *Fortnightly Review*, January 1894.

(J. D. B.)

Alexander, king of Servia (1876—), was born 14th August 1876. He succeeded to the crown on 6th March 1889, when his father, King Milan, abdicated and proclaimed him king of Servia under a regency until he should attain his majority at eighteen years of age. King Alexander on 13th April 1893, being then in his seventeenth year, made his notable *coup d'état* and took the royal authority into his own hands. After a banquet on that day he made a stirring appeal to the army, proclaimed his majority, and dismissed the regents and their ministry. His action was popular, and was rendered still more so by his appointment of a Radical ministry. In May 1894 King Alexander, by another *coup d'état*, abolished the constitution of 1889 and restored that of 1869, thus reinstating King Milan and Queen Natalie in their constitutional rights as members of the royal house of Obrenovitch. His attitude during the Turco-Greek war of 1897 was one of strict neutrality. In 1898 he appointed his father commander-in-chief of the Servian army, and from that time, or rather from his return to Servia in 1894 until 1900 ex-King Milan was regarded as the *de facto* ruler of the country. But on 21st July 1900 King Alexander publicly betrothed himself to Madame Draga Maschin, a widow, formerly a lady-in-waiting to Queen Natalie. The projected union aroused great opposition at first, and ex-King Milan resigned his post, an example followed by all the government officials; the marriage, however, was duly celebrated on 5th August,

and the king's firmness in the matter greatly strengthened his position, which was made even more secure by the death of his father shortly afterwards.

Alexander, William (1824—), Protestant Archbishop of Armagh and Primate of all Ireland, was born at Londonderry 13th April 1824, and educated at Tonbridge Grammar School and at Exeter and Brasenose colleges, Oxford. After holding several livings in the north of Ireland he was made bishop of Derry and Raphoe in 1867, and was elevated to the primacy in 1896. An eloquent preacher and the author of numerous theological works, he is best known to literature as a master of dignified and animated verse. His poems were collected in 1887 under the title of *St Augustine's Holiday, and other Poems*. His wife, who died in 1895, was also known as a writer of graceful poetry, and particularly for her hymn "There is a Green Hill far away."

Alexandra, Queen. See EDWARD VII.

Alexandretta, or ISKANDERÛN (*Alexandria ad Issum*), the principal port of the Aleppo vilâyet, founded by Alexander in memory of the battle of Issus. The town was formerly unhealthy, but since the drainage of the marshes and the provision of a better water-supply, its sanitary condition has greatly improved and trade is increasing. Population, 8000 (Moslems, 5500; Christians, 2500). It is the seat of a British vice-consulate. See ALEPPO.

Alexandria, the chief seaport and, next to Cairo, the largest city in Egypt. It suffered severely during the revolt of Arabi Pasha in June and July 1882, when, both before and after the bombardment of the forts by the British fleet, great disorders broke out in the town. On 11th June over 400 Europeans were massacred by the fanatical Mahommedans, and on the night following the bombardment (11th July) incendiary riots caused great loss of life and property, for which Egypt had eventually to raise £9,000,000 to meet the claims for compensation made chiefly by Europeans. Since then it has been visited by two epidemics of cholera (1883 and 1897). Nevertheless under the British occupation it has recovered its former commercial and industrial prosperity, as shown by the rapid increase of the population, which rose from 213,000 in 1882 to 320,000 in 1897, including over 46,000 Europeans, chiefly Greeks and Italians, and about 100 English families. Most of the foreign trade of Egypt passes through this seaport, the imports and exports of which advanced from £5,000,000 and £13,000,000 respectively in 1881 to £9,945,000 and £15,068,000 in 1899. The vessels entered were 3305 of 1,192,000 tons in 1881, and 2805 of 2,414,674 tons in 1899; the clearances for the corresponding years being 3250 of 1,304,000 tons and 2758 of 2,389,058 tons. In 1899 the British entries were 747 of 1,150,231 tons, and clearances 741 of 1,139,698 tons. Alexandria was the first Egyptian town provided with a municipal council, on which the government, the foreign merchants, and natives are represented. A great deal has been done to improve the town, which is provided with several new thoroughfares, electric light, and electric tramways, while the suburb of Ramlah has been greatly enlarged, and is now occupied chiefly by English residents. A new quay and promenade, extensive wharves and graving docks are also being constructed, while a projected channel 30 feet deep and 300 wide will enable large vessels to enter the port at all times. Amongst the scientific and literary establishments are the Egyptian institute, an athenæum, with courses of lectures, a public library, and an archæological museum. In the last-mentioned, founded in 1893, are now safely housed the antiquities, especially Greek and Roman, which are

from time to time brought to light in the district. During the excavations near Pompey's column in 1900 some monumental ruins were exposed, which have by some archaeologists been identified with the foundations of the great temple of Serapis. Alexandria is held by a British garrison of about 1000 men, including a battalion of infantry and artillery, under a British major-general.

Alexandria, a town in Rumania, situated in a rich grain-producing country, near the Danube, between Roshi-de-Vede and Zimnitza. It was founded by Prince Alexander Couza. Population (1900), 13,675.

Alexandria, a district town of Russia, government of Kherson, 93 miles S.W. of Poltava, on the Ingulets, with tanneries, tallow-houses, and soap and candle works. Population (1897), 14,002.

Alexandria, a manufacturing town of Dumbartonshire, Scotland, situated on the right bank of the river Leven, opposite Bonhill, by rail 19¼ miles W.N.W. of Glasgow. It contains the largest of the five Turkey red dyeing establishments recently amalgamated under one company. The public buildings include a public hall, the mechanics' institute library, an institute for men, with library and recreation rooms, and a similar institution for women. Population in 1881, 6173; 1891, 7796; 1901, 8392. Alexandria is in the parish of BONHILL, with the town of which name it is connected by a bridge which replaced in 1898 one bought three years earlier by the County Council from the Smollett family. Population of Bonhill town in 1901, 3922; of Bonhill parish, 14,581.

Alexandria, a city of Virginia, U.S.A., situated in 38° 48' N. lat. and 77° 02' W. long. Though within the limits of Alexandria county, it is independent of county government, is divided into four wards, and is entered by the Pennsylvania and the Southern railways, and by electric railway from Washington, with which it is also connected by ferry. The Civil War checked its growth, and the powerful rivalry of Washington, only seven miles distant, has held it almost at a standstill for a generation. The Chesapeake and Ohio Canal, which formerly extended to this place, now ends at Washington. The population in 1880 was 13,659, in 1890 it was 14,339, and in 1900 it was 14,528.

Alexandria, a city of Madison county, Indiana, U.S.A., a little north-east of the centre of the state, at the intersection of the Cleveland, Cincinnati, Chicago, and St Louis and the Lake Erie and Western railways. It has had a rapid growth, the population increasing from 715 in 1890 to 7221 in 1900.

Alexandria, a town of Louisiana, U.S.A., capital of Rapides Parish, on the south bank of the Red river, in the central part of the state, in a region devoted to the cultivation of sugar-cane and cotton. The population in 1890 was 2861; in 1900 it was 5648.

Alexandropol, or ALEXANDRAPOL (Turkish *Guleri*), a Russian town, fortress, and fortified camp in Transcaucasia, government of Erivan, near the junction of the Arpachai with the Aras, 30 miles by rail E.N.E. of Kars. It has an extensive fortified military camp, and six spacious caravanserais, besides considerable silk trade. Population (1885), 22,670; (1897), 32,020.

Alexandrovsk, the name of several towns in Russia: (1) New settlement of the government of Archangel, in the military harbour of Catherine (Ekaterinsk), on the Norman coast, 5 miles from the mouth of Kola Bay and 26 miles from Kola. It is a naval station. (2) District and town south of Ekaterinoslav, near the

left bank of the Dnieper, below its rapids, and on the railway to Sebastopol. It has great store-houses. Population (1897), 16,393. Opposite it is the island of Khortitsa, upon which was the renowned Sich (or Syech) of the Zaporog Cossacks. All its neighbourhood is strewn with *kurgans* (tumuli). (3) Russian village and fort, on the coast of the maritime province in Gulf De Castries, opposite Sakhalin island. It has a good harbour, hospital, and government store-houses, and trade with America.

Alexandrovsk-Crushevskaya, a Cossack village of Russia, province of the Don, 5 miles N.W. of Novocherkask, in the centre of the Grushevskiya anthracite mines. The stock of coal of the latter is estimated at 16,000,000 tons. About 645,000 tons are now extracted every year by about 13,100 workmen. Population of the village, 16,250 in 1897.

Alfortville, a town, arrondissement of Sceaux, department of Seine, 4 miles E.S.E. of Paris, at the confluence of the Seine and the Marne. India-rubber goods are manufactured, boat-building is carried on, and there are forges and rolling-mills. Population (1891), 7735; (1896), 11,410, (comm.) 11,614.

Alfred Ernest Albert, DUKE OF EDINBURGH, and DUKE OF SAXE-COBURG AND GOTHA, (1844-1900), second son and fourth child of Queen Victoria, was born at Windsor Castle, 6th August 1844. In 1856 it was decided that the prince, in accordance with his own wishes, should enter the navy, and a separate establishment was accordingly assigned to him, with Lieutenant Sowell, R.E., as governor. He passed a most creditable examination for midshipman in August 1858, and being appointed to the *Eruryalus*, at once began to work hard at the practical part of his profession. In July 1860, while on this ship, he paid an official visit to the Cape, and made a very favourable impression both on the colonials and on the native chiefs. On the abdication of Otho, king of Greece, in 1862, Prince Alfred was chosen by the whole people to succeed him, but political conventions of long standing rendered it impossible for the British Government to accede to their wishes. The prince therefore remained in the navy, and was promoted lieutenant 24th February 1863, and captain 23rd February 1866, being then appointed to the command of the *Galatea*. On attaining his majority in 1865, the prince was created duke of Edinburgh and earl of Ulster, with an annuity of £15,000 granted by Parliament. While still in command of the *Galatea*, the duke started from Plymouth, 24th January 1867, for his voyage round the world. On 11th June 1867, he left Gibraltar and reached the Cape on 24th July, and landed at Glenelg, South Australia, on 31st October. Being the first royal prince to visit Australia, the duke was received with the greatest enthusiasm. During his stay of nearly five months he visited Adelaide, Melbourne, Sydney, Brisbane, and Tasmania; and it was on his second visit to Sydney that, while attending a public picnic at Clonfert in aid of the Sailors' Home, an Irishman named O'Farrell shot him in the back with a revolver. The wound was fortunately not dangerous, and within a month the duke was able to resume command of his ship and return home. He reached Spithead on 26th June 1868, after an absence of seventeen months. The duke's next voyage was to India, where he arrived in December 1869. Both there and at Hong Kong, which he visited on the way, he was the first British prince to set foot in the country. The native rulers of India vied with one another in the magnificence of their entertainments during the duke's stay of three months. On 23rd January 1874 the marriage of the duke to the Grand Duchess Marie Alexandrovna, only

daughter of Alexander II., emperor of Russia, was celebrated at St Petersburg, and the bride and bridegroom made their public entry into London on 12th March. The duke still devoted himself to his profession, showing complete mastery of his duties and unusual skill in naval tactics. He was promoted rear-admiral, 30th December 1878; vice-admiral, 10th November 1882; admiral, 18th October 1887; and received his baton as admiral of the Fleet, 3rd June 1893. He commanded the Channel Fleet, 1883-84; the Mediterranean Fleet, 1886-89; and was commander-in-chief at Devonport, 1890-93. He always paid the greatest attention to his official duties, and was most efficient as an admiral.

On the death of his uncle, Ernest II., duke of Saxe-Coburg and Gotha, 22nd August 1893, the vacant duchy fell to the duke of Edinburgh, for the Prince of Wales had renounced his right to the succession. At first regarded with some coldness as a "foreigner," he gradually gained

popularity, and by the time of his death, 30th July 1900, he had completely won the good opinion of his subjects. The duke was exceedingly fond of music, and an excellent violinist, and took a prominent part in establishing the Royal College of Music. He was also a keen collector of glass and ceramic ware, and his collection, valued at half a million of marks, was presented by his widow to the "Veste Coburg," near Coburg. When he became duke of Saxe-Coburg he surrendered his English allowance of £15,000 a year, but the £10,000 granted in addition by Parliament on his marriage he retained in order to keep up Clarence House. The duke had one son, who died unmarried, 6th February 1899, and four daughters. The third daughter, Princess Alexandra Louisa Olga Victoria, married the hereditary Prince Ernest of Hohenlohe-Langenburg, who became regent of the duchy of Coburg during the minority of the deceased duke's nephew, the young duke of Albany, to whom the succession fell. (G. F. B.)

A L G Æ.

THE Latin word *Alga* seems to have been the equivalent of the English word "seaweed," and probably stood for any or all of the species of plants which form the "wrack" of a seashore. When the word "Algæ" came to be employed in classification as the name of a class, an arbitrary limitation had to be set to its signification, and this was not always in keeping with its original meaning. The absence of differentiation into root, stem, and leaf, which prevails among seaweeds, seems, for example, to have led Linnæus to employ the term in the *Genera Plantarum* for a sub-class of *Cryptogamia*, the members of which presented this character in a greater or less degree. Of the fifteen genera included by Linnæus among Algæ, not more than six, viz.:—*Chara*, *Fucus*, *Ulva*, and *Conferva*, and in part *Tremella* and *Byssus*, would to-day, in any sense in which the term is employed, be regarded as Algæ. The excluded genera

Classification.

are distributed among the Liverworts, Lichens, and Fungi; but notwithstanding the great advance in knowledge since the time of Linnæus, the difficulty of deciding what limits to assign to the group to be designated *Algæ* still remains. It arises from the fact that Algæ, as generally understood, do not constitute a homogeneous group, suggesting a descent from a common stock. Among them there exist, as will be seen hereafter, many well-marked but isolated natural groups, and their inclusion in the larger group is generally felt to be a matter of convenience rather than the expression of a belief in their close inter-relationship. Efforts are therefore continually being made by successive writers to exclude certain outlying sub-groups, and to reserve the term *Algæ* for a central group reconstituted on a more natural basis within narrower limits.

It is perhaps desirable, in an article like this, to treat of Algæ in the widest possible sense in which the term may be used, an indication being at the same time given of the narrower senses in which it has been proposed to employ it. Interpreted in this way, the place of Algæ in the vegetable kingdom may be shown by means of a table:—

The Vegetable Kingdom	Cryptogamia	Thallophyta	Myxomycetes
			Fungi
Phanerogamia		Bryophyta	Algæ
			Pteridophyta
			Gymnosperms
			Angiosperms

Algæ in this wide sense may be briefly described as the aggregate of those simpler forms of plant life usually

devoid, like the rest of the *Thallophyta*, of differentiation into root, stem, and leaf; but, unlike other *Thallophyta*, possessed of a colouring matter, by means of which they are enabled, in the presence of sunlight, to make use of the carbonic acid gas of the atmosphere as a source of carbon. It is true that certain *Bryophyta* (*Marchantiaceæ*, *Anthocerotæ*) possess a thalloid structure similar to that of *Thallophyta*, and are at the same time possessed of the colouring matter of the Green Algæ. Their life-cycle, however, the structure of the reproductive organs, and their whole organization proclaim them to be *Bryophyta*. (See MUSCINEÆ, ninth ed., and BRYOPHYTA.) On the other hand certain undoubted animals (*Stentor*, *Hydra*, *Bonellia*) are provided with a green colouring matter by means of which they make use of atmospheric carbonic acid. A more important consideration is the occasional absence of this colour in species, or groups of species, with, in other respects, Algal affinities. Such aberrant forms are to be regarded in the same light as *Cuscuta* and *Orobanchaceæ*, for example, among Phanerogams. As these non-green plants do not cease to be classed with other Phanerogams, so must the forms in question be retained among Algæ. In all cases the loss of the colouring matter is associated with an incapacity to take up carbon from so simple a compound as carbonic acid.

Further discussion of the general characters of Algæ will be deferred in order to take a brief survey of the subdivisions of the group. For this purpose, there will be adopted the classification of Algæ into four sub-groups, founded on the nature of the colouring matters present in the plant:—

1. CYANOPHYCÆ, or Blue-green Algæ.
2. CHLOROPHYCÆ, or Green Algæ.
3. PHÆOPHYCÆ, or Brown Algæ.
4. RHODOPHYCÆ, or Red Algæ.

The merits and demerits of this system will appear during the description of the characters of the members of the several subdivisions.

1. CYANOPHYCÆ.¹—This group derives its name from the circumstance that the cells contain in addition to the green colouring matter, chlorophyll, a blue-green colouring matter to which the term phycocyanin has been applied. To the eye, however, members of this group present a greater variety of colour

¹ Includes (exclusive of Bacteriaceæ) :—

1. *Coccolgonæ*—2 families, 29 genera, 253 species.

2. *Hormogonæ*—6 families, 59 genera, 701 species.

(Engler and Prantl's *Pflanzenfamilien*).

than those of any other—yellow, brown, olive, red, purple, violet, and variations of all these being known. They undoubtedly represent the lowest grade of Algal life, and their distribution rivals that of the Green Algae. They occur in the sea, in fresh water, on moist earth, on damp rocks, and on the bark of trees. Certain species are regularly found in the intercellular spaces of higher plants; such are species of *Nostoc* in the thallus of *Anthoceros*, the leaves of *Azolla*, and the roots of Cycads. Many of them enter into the structure of the lichen-thallus, as the so-called gonidia. It is remarkable that species belonging to the *Oscillatoriaceæ* are known to flourish in hot springs, the temperature of which rises as high as 85° C.

The thallus may be unicellular or multicellular. When unicellular, it may consist of isolated cells, but more commonly the cells are held together in a common jelly (*Chroococcaceæ*) derived from the outer layers of the cell-wall. The multicellular species consist of filaments, branched or unbranched, which arise by the repeated division of the cells in parallel planes, no formation of mucilage occurring in the dividing walls. Such filaments may not give rise to mucilage on the lateral surface either, in which case they are said to be free; when mucilage does occur on the lateral wall, it appears as the sheath surrounding either the single filament, or a sheaf of filaments of common origin. The mucilage may also form an embedding substance similar to that of *Chroococcaceæ*, in which the filaments lie parallel or radiate from a common centre (*Rivulariaceæ*). The cells of the filament may be all alike, and growth may occur equally in all parts (*Oscillatoriaceæ*); or certain cells (heterocysts) may become marked off by their larger size and the transparency of their contents; in which case growth may still be distributed equally throughout (*Nostoc*), or the filament may be attached where the heterocyst arises, and grow out at the opposite extremity into a fine hair (*Rivulariaceæ*). An African form (*Camptothrix*), devoid of heterocysts and hair-like at both extremities, has recently been described. Branching has been described as "false" and "true." The former arises when a filament in a sheath, either in consequence of growth in length beyond the capacity of the sheath to accommodate it, or because of the decay of a cell, becomes interrupted by breaking, and the free ends slip past one another. "True" branching arises only by the longitudinal division of a cell of a filament and the lateral outgrowth of one of the cells resulting from the division (*Strosiphonaceæ*).

The nature of the contents of the cells of *Cyanophyceæ* has given rise to considerable controversy. The cells are for the most part exceedingly minute, and are not easy to free from their colouring matters, so that investigation has been attended with great difficulty. Occupying as these Algae do perhaps the lowest grade of plant life, it is a matter of interest to ascertain whether a nucleus or chromatophore is differentiated in their cells, or whether the functions and properties of these bodies are diffused through the whole protoplast. It is certain that the centre of the cell, which is usually non-vacuolated, is occupied by protoplasm of different properties from the peripheral region; and Fischer has further established the fact that the peripheral mass, which is a hollow sphere in spherical cells, and either a hollow cylinder or barrel-shaped body in filamentous forms, must be regarded as the single chromatophore of the *Cyanophyceous* cell. But whether the central mass is anything more than protoplasm laden with the products of assimilation still remains uncertain. Among other contents of the cell, fatty substances and tannin are known. A curious adaptation seems to occur in certain floating forms, in the presence of a gas-vacuole, which may be made to vary its volume with varying pressure. There is evidence that the dividing wall of filamentous forms is deeply pitted, as is found to be the case in Red Algae. Reproduction is chiefly effected by the vegetative method. Asexual reproductive cells are not infrequent, but sexual reproduction even in its initial stages is unknown. Nor is motility by means of cilia known in the group. In the unicellular forms, cell-division involves multiplication of the plant. In all the multicellular plants of this group which have been adequately investigated, vegetative multiplication by means of what are known as hormogonia has been found to occur. These are short segments of filaments consisting of a few cells which disengage themselves from the ambient jelly, if it be present, in virtue of a peculiar creeping movement which they possess at this stage. After a time they come to rest and give rise to new colonies. True reproduction of the asexual kind occurs, however, in the formation of sporangia, particularly in the *Chamaesiphonaceæ*. Here the contents of certain cells break up endogenously into a great number of spores, which are distributed as a fine dust. Resting spores are also known. In these cases certain cells of a colony of unicellular plants or of the filaments of multicellular plants enlarge greatly and thicken their wall. When unfavourable external conditions supervene and the ordinary cells become atrophied, these cells persist and reproduce the plant with the return of more favourable conditions. The *Oscillatoriaceæ* are capable of a peculiar oscillatory movement, which has earned for

them their name, and which enables them to move through considerable distances. It is not clear how the movement is effected, though it has frequently been the subject of careful investigation.

With the *Cyanophyceæ* must be included, as their nearest allies, the *Bacteriaceæ*. Notwithstanding the absence of chlorophyll, and the consequent parasitic or saprophytic habit, *Bacteriaceæ* agree in so many morphological features with *Cyanophyceæ* that the affinity can hardly be doubted.

They are, however, not further considered here, since they are separately dealt with in this work. (See BACTERIOLOGY.)

2. CHLOROPHYCEÆ.¹—This group includes those Algae in which the green colouring matter, chlorophyll, is not accompanied by a second colouring matter, as it is in other groups. It consists of three subdivisions:—*Conjugatæ*, *Euchlorophyceæ*, and *Characeæ*. Of these the first and last are relatively small and sharply defined families, distinguished from the second family, which forms the bulk of the group, by characters so diverse that their inclusion with them in one larger group can only be justified on the ground of convenience. *Euchlorophyceæ* are made up in their turn of three series of families:—*Protococcales*, *Confervales*, and *Siphonales*. *Chlorophyceæ* include both marine and freshwater plants. *Conjugatæ*, *Protococcales*, and *Characeæ* are exclusively freshwater; *Confervales* and *Siphonales* are both freshwater and marine, but the latter group attains its greatest development in the sea. Some *Chlorophyceæ* are terrestrial in habit, usually growing on a damp substratum, however. *Trentepohlia* grows on rocks and can survive considerable desiccation. *Phycopeltis* grows on the surface of leaves, *Phyllobotium* and *Phyllosiphon* in their tissues. *Gomontia* is a shell-boring Alga, *Dermatophyton* grows on the carapace of the tortoise, and *Trichophilus* in the hairs of the sloth. Certain *Protococcales* and *Confervales* exist as the gonidia of the lichen-thallus.

The thallus is of more varied structure in this group than in any other. In the simplest case it may consist of a single cell, which may remain free during the whole or the greater part of its existence, or be loosely aggregated together within a common mucilage, or held together by the adhesion of the cell-walls at the surface of contact. These aggregations or colonies, as they are termed, may assume the form of a plate, a ring, a solid sphere, a hollow sphere, a perforate sphere, a closed net, or a simple or branched filament. It is not easy in all cases to draw a distinction between a colony of plants and a multicellular individual. In a *Volvox* sphere, for example, there is a marked protoplasmic continuity between all the cells of the colony. The *Ulvaceæ*, the thallus of which consists of laminae one or more cells thick, or hollow tubes, probably represent a still more advanced stage in the passage of a colony into a multicellular plant. Here there is some amount of localization of growth and distinction of parts. It is only in such cases as *Volvox* and *Ulvaceæ* that there is any pretension to the formation of a true parenchyma within the limits of the *Chlorophyceæ*. In the whole series of the *Confervales*, the thallus consists of filaments branched or unbranched, attached at one extremity, and growing almost wholly at the free end. The branches end in fine hairs in *Chaetophoraceæ*. In *Colocephataceæ* the branches are often welded into a plate, simulating a parenchyma. In all *Conjugatæ* and most *Protococcales*, and in the bulk of the *Confervales*, the thallus consists of a cell or cells, the protoplast of which contains a single nucleus. In *Hydrodictyceæ*, *Cladophoraceæ*, *Sphaeropleaceæ*, and *Gomontiacæ* this is no longer the case. Instead of a single relatively large nucleus, each cell is found to contain many small nuclei, and is spoken of as a *cænocyte*. This character becomes still more pronounced in the large group of the *Siphonales*. *Valoniaceæ* and *Dasycladaceæ* are partially septate, but elsewhere no cellulose partitions occur, and the thallus is more or less the continuous tube from which the group is named. Yet the Siphonaceous Algae may assume great variety of form and reach a high degree of differentiation. *Protosiphon* and *Botrydium*, on the one hand, are minute vesicles attached to muddy surfaces by rhizoids; *Caulerpa*, on the other, presents a remarkable instance of the way in which much the same external morphology as that of cormophytes has been reached by a totally different internal structure. Many *Siphonales* are encrusted with lime like *Corallina* among Red Algae. *Penicillus* is brush-like, *Halimeda* and *Cymopolia* are jointed, *Acetabularia* has much the same external form as an expanded *Coprinus*, *Neomeris* simulates the fertile shoot of *Equisetum* with its densely-packed whorled branches, and in *Microdictyon*, *Anadyomene*, *Struvea*, and *Boodlea* the branches, spreading in one plane, become hound together in a more or less close network.

¹ Chlorophyceæ include:—

1. Confervoides—12 families, 77 genera, 1021 species.
2. Siphonae—9 families, 26 genera, 271 species.
3. Protococcoides—2 families, 90 genera, 342 species.
4. Conjugatæ—2 families, 33 genera, 1296 species.

(De Toni's *Sylloge Algarum*.)

5. Characeæ—2 families, 6 genera, 181 species.

(Engler and Prantl's *Pflanzenfamilien*.)

Characeæ are separated from other *Chlorophyceæ* by a long interval, and present the highest degree of differentiation of parts known among Green Algae. Attached to the bottom of pools by means of rhizoids, the thallus of *Characeæ* grows upwards by means of an apical cell, giving off whorled appendages at regular intervals. The appendages have a limited growth; but in connexion with each whorl there arise, singly or in pairs, branches which have the same unlimited growth as the main axis. There is thus a close approach to the external morphology of the higher plants. The streaming of the protoplasm, known elsewhere among *Chlorophyceæ*, is a conspicuous feature of the cells of *Characeæ*.

The *Chlorophyceæ* excel all other groups of Algae in the magnitude and variety of form of the chlorophyll-bodies. In *Ulva* and *Mesocarpus* the chromatophore is a single plate, which in the latter genus places its edge towards the incident light; in *Spirogyra* they are spiral bands embedded in the primordial utricle; in *Zygnema* they are a pair of stellate masses, the rays of which branch peripherally; in *Edogonium* they are longitudinally-disposed anastomosing bands; in *Desmids* plates with irregular margins; in *Cladophora* polyhedral plates; in *Vaucheria* minute elliptical bodies occurring in immense numbers. Embedded in the chromatophore, much in the same way as the nucleus is embedded in the cytoplasm, are the *pyrenoids*. Unknown in *Cyanophyceæ* and *Phaeophyceæ*, known only in *Bangiaceæ* and *Nemalion* among *Rhodophyceæ*, they are of frequent occurrence among *Chlorophyceæ*, excepting *Characeæ*. Sometimes several pyrenoids occur in each chloroplast, as in *Mesocarpus* and *Spirogyra*; sometimes only an occasional chloroplast contains pyrenoid at all, as in *Cladophora*. The pyrenoid seems to be of proteid nature and gelatinous consistency, and to arise as a new formation or by division of pre-existing pyrenoids. When carbon-assimilation is active, starch-granules crowd upon the surface of the pyrenoid and completely obscure it from view.

Special provision for vegetative multiplication is not common among *Chlorophyceæ*. *Valonia* and *Caulerpa* among *Siphonales* detach portions of their thallus, which are capable of independent growth. In *Caulerpa* no other means of multiplication is as yet known. In *Characeæ* no fewer than four methods of vegetative reproduction have been described, and the facility with which buds and branches are in these cases detached has been adduced as an evidence of affinity with *Bryophyta*, which, as a class, are distinguished by their ready resort to vegetative reproduction.

With regard to true reproduction, which is characterized by the formation of special cells, the group *Euchlorophyceæ* is characterized by the production of zoospores; that is to say, cells capable of motility through the agency of cilia. Such ciliary motion is known in the adult condition of the cells of *Volvocaceæ*, but where this is not the case the reproductive cells are endowed with motility for a brief period. The zoospore is usually a pyriform mass of naked protoplasm, the beaked end of which where the cilia arise is devoid of colouring matter. A reddish-brown body, known as the eyespot, is usually situated near the limits of the hyaline portion, and in the protoplasm contractile vacuoles similar to those of lower animals have been occasionally detected. The movement of the zoospore is effected by the lashing of the cilia, and is in the direction of the beak, while the zoospore slowly rotates on its long axis at the same time. Usually two cilia are present; in *Botrydium* and *Hydrodictyon* only one is present; in certain species of *Cladophora* four; in *Dasycladus* a chaplet, and in *Edogonium* a ring of many cilia. The so-called zoospore of *Vaucheria* is a cœnocyte covered over with paired cilia corresponding in position to nuclei lying below. In all other cases, zoospores are uninucleate bodies. Zoospores arise in cells of ordinary size and form termed zoosporangia. In unicellular forms (*Sphaerella*) the thallus becomes transformed into a zoosporangium at the reproductive stage. In the zoosporangia of *Edogonium*, *Tetraspora*, and *Coleochæte*, the contents become transformed into a single zoospore. In most cases repeated division seems to take place, and the final number is represented by some power of two. In cœnocytic forms the zoospores would seem to arise simultaneously, probably because many nuclei are already present. The escape of zoospores is effected by the degeneration of the sporangial wall (*Chaetophora*), or by means of a pore (*Cladophora*), or a slit (*Pediastrum*), or a circular fracture (*Edogonium*). Zoospores are of two kinds:—(1) Those which come to rest and germinate to form a new plant; these are asexual and are zoospores proper. (2) Those which are incapable of germination of themselves, but fuse with another cell, the product giving rise to a new individual; these are sexual and are zoogametes. When two similar zoogametes fuse, the process is conjugation, and the product a zygospore. Usually, however, only one of the fusing cells is a zoogamete, the other gamete being a much larger resting cell. In such a case the zoogamete is male, is called an antherozoid or spermatozoid, and arises in an antheridium; the larger gamete is an oosphere and arises in an oogonium. The fusion is now known as fertilization, and the product is an oospore. Reproduction by conjugation is also known as

isogamy, by fertilization as oogamy. When zoospores come to rest, a new cell is formed and germination ensues at once. When zygospores and oospores are produced a new cell-wall is also formed, but a long period of rest ensues. All investigation goes to show that an essential part of sexual union is the fusion of the two nuclei concerned. It is interesting to know, on the authority of Oltmanns, that when the oosphere is forming in the oogonium of *Vaucheria*, there is a retrocession of all the included nuclei but one. That the antherozoid of *Vaucheria* contains a single nucleus had been inferred before.
